It is always interesting to watch an excavation in Egypt at any stage of its progress, for so many treasures of so many kinds lie everywhere in the preserving sands. Here, at Deir el Bahari, the diggers, drawn from Theban villages, have been tomb-robbers to a man, and have lynx eyes for small antiquities. Pecking away at the lower layers of the mounds, they let hardly a minute pass without picking up scarabs, amulets, beads, or bits of that wonderful blue-glazed ware which ranks among the finest products of the ancient world. Here a fragment of potsherd, inscribed with Coptic writing, slides down the earth slope; there rolls a limestone chip covered with Demotic characters. These are the archives and, it seems, also the library-catalogue of the monastery built here in the early days of Christianity. Now and then a refuse-heap is reached, and bits of papyrus, Greek, Demotic and Coptic, are taken out in handfuls, together with broken objects of every sort and kind and many precious fragments of sculptured walls. Perhaps the patient fellaheen pilfer a little; men who habitually use their mouths as purses can easily hide a scarab or a charm. The Luxor tourists are ready to give so many times their real value for these little objects that the archaeologist cannot afford to bid against dealers who purvey for such a market. But much can be done by watchfulness—more perhaps by indirect play on the hopes and fears of the fellaheen, who is by nature honest, if weak in the face of prolonged temptation and opportunity. The question of honesty apart, he is at any rate as good a workman as could be found anywhere for such work as scientific excavation. He is watchful, careful and light-handed; he needs little driving, for he has not that cunning given to the Greek to enable him to shirk, and he amuses himself vastly by one means or another while he works, singing, joking and teasing. He is best left to dig after his own fashion with a feeble hoe, for it is no bad means to the end in view. Pickaxe and spade would break where the *turi* does no harm, and if he can be kept to his level cutting, and a mole-like propensity for burrowing (which betrays the habit of tomb-digging) checked, he will clear away for *5d.* a vast amount of packed earth in a day, and withal find the antiquities it contained. These bowed bronze figures, however, that stoop forward in a rising mist of dust, are not the only agents which science employs. Behind them are twice as many boy basket bearers, unconsciously graceful as youths on a Greek frieze. Here a full car is being pushed groaning down the line by four adult children delighted with their rolling toy; there an empty one is coming back at a run, and will probably be run off the rails presently by its excited drivers. At some little distance a sculptured wall is being rebuilt by native masons, who dispense with scaffolding and squat sparrow like on the topmost course, in that attitude moving heavy stones with perfect ease. Every one is singing some one of the old choruses that every Arab knows, a line or two improvised here and there by the fogleman about the stone, or the mummies, or the steamers on the distant Nile, or anything that strikes his eye or fancy for the moment. Towards sunset the chorus grows louder, all eyes meet on the master's lips; and one syllable of the word of dismissal is hardly framed before men and boys are off, sliding down the earth-shoots, jumping over stones, shouting as though bound for something better than onions and bread and labour again at sunrise to-morrow.

The hot season and the fast month, Ramadan, break off the work in the middle of March. By then the mounds on the central terrace will have disappeared, and the sculptured west wall, the pillared hall with its funeral scenes, and the colonnade will be visible again, as they have not been for many centuries. In December next another season will open, the lesser accumulations on the southern side of the temple be attacked, and the costly rebuilding operations continued on the upper terrace. If the present undertaking can be carried through the Egypt Exploration Fund will have the credit of promoting a unique monument to the select first rank of the spectacles of Egypt, and its publication of the reliefs and paintings, as well as all the minor treasures found and to be found, will be more complete and not less artistic than the magnificent volumes which French munificence has produced.

ARCHITECT'S PLANS IN CAPE COLONY.

IN the Supreme Court, Cape Town, before the full bench on the 21st ult., the case of *De Witt v. Cape Canning Company* was heard. Mr. Schreiner, with whom was Mr. Watermeyer, appeared for plaintiff, and Mr. Searle, with whom was Mr. Jones, for defendants. The *Cape Argus* gives the following report:—

This was an action brought by Mr. A. M. de Witt, architect, of Cape Town, against Mr. H. Batezat, in his capacity as secretary of the Cape Canning Company, to recover the sum of 77*l.* 8*s.* as remuneration for work and labour performed on behalf of the company by the plaintiff, at the special instance and request of Mr. Strasburger, the manager of the company, by preparing plans and specifications of a factory and cottage which it was proposed by the company to erect in the Dock Road. In October last Mr. Strasburger called upon plaintiff and asked him to prepare plans and specifications of the proposed factory and cottage. The plaintiff accepted the appointment, and the work was completed about the close of the month. Advertisements were inserted in the newspapers for tenders for the work on the basis of the plaintiff's plans and specifications. About November 8 the plaintiff was notified that his plans had been accepted, and that the work was to be proceeded with. His account was 77*l.* 8*s.*, which was 2½ per cent. on the tender of Dixon. The defendants repudiated all responsibility, and the issue before the Court was simply this:—The defendants contended that the plaintiff undertook to prepare the plans knowing that he was competing with other architects, and knowing also that he would not be entitled to any remuneration unless his plans were accepted. The plaintiff wholly denied anything of the kind, and had never entered into competition with other architects.

Mr. A. M. de Witt deposed that he had been practising as an architect in Cape Town since 1879, and was architect for the Lobster Factory at Woodstock. About October 13 last Mr. Strasburger, manager of the Cape Canning Company, called upon him and said he wanted him to draw up plans for a fish canning factory, which was about to be started by some Cape Town merchants. In company with Strasburger he visited the site of the proposed factory, at the foot of Bree Street. Strasburger gave him the dimensions of the various rooms, and he took down the particulars in his pocket-book. There was to be a factory and a cottage for the manager. During the interview Strasburger informed him that plans had been prepared by Messrs. Stent and Ransome, and also that Mr. Freeman had been communicated with. He told witness that the plans of Messrs. Stent & Ransome had not been approved of, and that they had sent in amended plans, but these were also rejected. Strasburger said that he supposed, as Freeman had not sent in any plans, he did not care about the job. He never intimated to witness in any way that he was supposed to be competing with any other architect. He had never done that sort of thing, but he might have accepted on those terms. He returned to his office, and with the assistance of his clerk, Mr. Perkins, set about drawing up the plans. A day or two afterwards, while making the sketch, it struck him that some improvement could be effected, and he called at the office where he found Mr. Batezat. The improvement he suggested was that rails should be placed on the floors for the trolleys to run on. Batezat said he knew nothing about this, witness had better consult Strasburger. During this interview Batezat showed him the plans sent in by Stent & Ransome, and also showed him some letters written by them as to the probable cost of erecting the factory. Batezat and Strasburger frequently visited his office, making suggestions and giving instructions. On October 23 he wrote a letter covering the plans, draughts and specifications. He estimated that the cost of the factory would be about 3,000*l.*, and that of the cottage 700*l.*, and that under favourable conditions the buildings could be completed in three and a half months. A couple of days afterwards Batezat, accompanied by Herbert, one of the shareholders, called upon him, bringing back the plans and specifications. They said that the matter had been laid before the Board, and that the cost of the factory had been approved of, but that the cost of the cottage must be reduced to about 500*l.* Witness said that if the dimensions of the cottage were reduced the work might be carried out for that sum. On October 30 he sent in an amended plan, and also prepared bills of quantities on the special instructions of Strasburger. He had some conversation with Batezat and Strasburger about the roof, and said that an iron roof could be obtained from England. He communicated with Mr. Cranmer, his agent in London, as to the cost, and received a reply by cable that he would deliver the roof on the spot for the sum of 1,000*l.* On October 31 an advertisement appeared in the *Cape Argus*, signed by the secretary to the defendant company, inviting tenders for the erection of a factory and buildings in the Dock Road, to be sent in by noon of Saturday, November 4, and stating that the plans and specifications could be seen at the office of the company, Selwyn Chambers, St. George's Street. Strasburger brought him the paper and asked him if the advertisement was properly drawn, and he said no.

He drew up another, which was inserted in the *Argus* on the following day. Tenderers came to his office, and he gave them bills of quantities. On November 4 he called at the office of the company, and asked Batezat who was the successful tenderer. Batezat read out those which had come to hand, and said that two more were to come in, and that time was extended until the following Monday. He asked witness if Dixon was a good man to employ, and witness expressed a favourable opinion. On the Monday witness went to the company's office and met Strasburger there; he wanted to know if wood would be cheaper than iron for the roof. His reply was that probably wood would be 100*l.* cheaper. Batezat and Strasburger said they were going to a meeting of the shareholders, and witness proposed to accompany them, but they did not desire him to do so, stating that if he was allowed to be present Ransome and Freeman would also claim to be there, as they also had sent in plans. This was the first he heard about these plans. In the afternoon he met the Hon. Mr. Graaff, one of the directors, who asked him if Dixon was a good man, and he said yes, at the same time pointing to several buildings which had been erected by him. On October 18 he inquired if his plans had been accepted, and the reply was that his plans had been submitted to the meeting with those of Ransome and Freeman, and it was decided to accept the plans of the last-named architect. On the same day his plans and other documents were returned to him. On the following day he returned the plans to the company, accompanied by a demand for payment, basing his claim on the amount of Dixon's tender. To this a reply came to the effect that witness had agreed to enter into competition with other architects, and that as his plans were deemed unsuitable he could not expect any remuneration and his account was returned. On November 16, Messrs. Van Zyl & Buissonne wrote to the defendants, denying the statement that their client entered into any competition, and intimating that if the account was not settled by the 18th legal proceedings would be instituted. Witness had inspected Freeman's plans; they were not copies of his, but on the same lines.

Cross-examined: He was aware that the plans would have to be submitted to the meeting of shareholders. He considered that if he was asked to send in plans he was entitled to payment whether they were accepted or not. Strasburger said nothing to him about other plans being sent in, or that the shareholders would have to decide on the rejection or otherwise of the plans. These competitions between architects were unusual. He was aware that the Claremont municipality was calling for plans by competition, but that was a public matter; but if architects were privately asked to send in plans they were entitled to some recompense. He sent in amended plans because the cost of the erection of the cottage was considered too much.

Mr. W. T. C. Perkins deposed that he was a clerk in the employ of the plaintiff, and had been engaged in preparing the plans connected with the present action. He was present on various occasions when Batezat and Strasburger came to the office, and gave instructions in detail as to how the plans were to be carried out.

Mr. A. J. Dixon, builder and contractor, deposed that he saw the advertisement calling for tenders for the erection of the canning factory, and called at the company's office for information. He saw no plans there except those of the plaintiff. He saw Batezat, who gave him all required information, and told him if he wanted more he must go and see the plaintiff. He said nothing whatever about any other architects. He saw Batezat on November 6, when he told him that his tender was the lowest, and that he stood as good a chance as anyone else of being the lucky man.

Messrs. C. Williams, J. Starck, R. Mitchell, H. J. Hunter and G. Clark, all builders and contractors, gave somewhat similar evidence.

Mr. J. Parker deposed that he was an architect. He considered that 2½ per cent. on the amount of Dixon's tender was a fair and reasonable charge. If plans were not approved of, the architect was entirely at the mercy of his client. In England approval would be the test of recovery. He had always received money, even when his plans had not been approved.

Cross-examined: If tenders were called for he would consider that the plans had been approved of. He had gone in for competitions among architects. In many cases architects spent months in drawing plans for large buildings, and got nothing if their plans were not accepted.

Mr. G. Ransome deposed that he was invited to send in plans, and knew that he was taking part in a competition. The names of Messrs. Stent and Freeman were mentioned as competitors, but the name of the plaintiff was not mentioned. He considered that 2½ per cent. was a fair and reasonable charge, provided the plans were accepted. He got nothing for drawing his plans. If tenders were called for he would look upon that as an acceptance of the plans.

Cross-examined: If the plans of an architect were accepted, the usual form of the advertisement disclosed his name and

stated that all information could be obtained from him. He made no claim on the defendants; he took the chance of being successful.

For the defence was called Mr. H. Batezat, who deposed that he was secretary of the defendant company, which was formed in September last. On October 24 a meeting of the shareholders was held to consider the plans sent in by Ransome, Stent, Freeman and the plaintiff. He told the plaintiff that there were other people preparing plans, and that no favour would be shown to anybody; he also informed him that all plans would have to be submitted to the meeting. The plaintiff acquiesced, and said that as he had already dealt with the Woodstock Factory he could do as well, if not better, with this building. One afternoon the plaintiff came to his office and asked for Strasburger, who was not in. Ransome's plans were lying on the desk, and the plaintiff requested, and was allowed, to inspect them. He said, "Isn't it a shame? He has actually copied the designs of my factory at Woodstock." Witness replied that Strasburger had called upon all the architects to furnish plans, and some of them must be pretty similar. After the meeting of October 24 he called for tenders, in accordance with instructions from the shareholders. On the day of the meeting he saw the plaintiff, who said he would be present. Witness replied, "If you are to be present, then Freeman and Ransome must also be there. You know very well that they have sent in plans." When the plans were submitted to the meeting, those of Freeman were accepted. He considered it to be a huge joke on the part of the plaintiff when he said that he was not aware that there was a competition.

Mr. C. Freeman deposed that he was one of those who sent in plans. If his plans had not been accepted he would not have made any claim on the company. The charge of $2\frac{1}{2}$ per cent. was a fair and reasonable one if the plans were accepted. If the work was not commenced the plans were very rarely charged for.

Mr. Searle said he had no further evidence to offer in the absence of Mr. Strasburger, whose departure from England had been delayed until March 3.

The Court directed that the further hearing of the case should stand over until April 13 next.

LOADS ON FLOORS OF AMERICAN OFFICES.

THE following explanation of the calculations adopted for the loads in the high office buildings of Chicago has been contributed to the *American Architect* by Mr. W. L. B. Jenney, architect:—

In calculating the steel-skeleton construction for an office-building, it is our aim to provide for all the dead-load and for the maximum actual live-load that will obtain. This last can only be reached by actual estimates. The observations of Mr. Emperger would seem to be theoretical. An examination in the building, we believe, will demonstrate there in New York, as well as here, that the live-load provided for, of 70 lbs. per square foot, does not obtain in any office in the building, and this extreme figure is used because of the possibility of an office being used for a gathering or meeting of as many as could even find comfortable standing-room, or a rush into a room or rooms, due to some special momentary attraction, and particularly in Chicago to satisfy the Building Ordinance. In such cases it would be best that a beam could be loaded temporarily its whole length with the maximum load of 70 lbs. per square foot, but that the girders should have the full maximum load necessitates that at the same time two or more beams assembled to the girder on each side should be all loaded with this maximum load at one and the same time, which cannot be reasonably presumed, hence the reduction of the live-load of, say, 10 or 20 per cent.

In regard to the columns. The only columns in the building that we can reasonably presume will ever carry the maximum load are the attic columns supporting the roof, which may be loaded exceptionally with a live-load of say 40 lbs. per square foot on the roof, consisting of snow and ice. This we deem sufficient even in Chicago, because these important buildings are in charge of a custodian under whom is a head janitor and chief engineer. In case snow-storms follow each other without much diminution of former falls of snow or frozen rain, it will be removed by the force whose duty it is to watch for such conditions, so that 40 lbs. is deemed to be sufficient. None of the offices are ever loaded to the calculated capacity of 70 lbs. per square foot.

Messrs. Blackall and Everett made numerous estimates of the actual live-loads in office buildings. Live-loads were found to range from a maximum in one single instance of about 40 lbs. to a minimum in several instances of 5 lbs. A live-load of 20 lbs. per square foot on each floor would exceed the average. An estimate made by the George A. Fuller Company, the leading building contractors of Chicago, gave but 6 lbs. per square foot with the office comfortably full, with 9 lbs. as an extreme maximum.

In offices and in hotel buildings so much space is taken up by light, though bulky, furniture that the live-loads are very low. In well-appointed fireproof buildings there are vaults which form a part of the dead-load in every suite of offices, so that there are few or no safes. The heaviest load is generally found in the lawyers' offices, consisting of books. Even in theatres Mr. Blackall quotes the heaviest load obtainable as but 58 lbs., so that the 70 lbs. per square foot which is used in calculating the beams in our office buildings is forced upon us by the Ordinance, and is fully 20 per cent. above what we would be justified in using. The foregoing, we believe, is a full justification of our methods of calculation.

In warehouses actual estimates must be made of the loads they are intended to carry. It should neither be too light nor too heavy, for if too heavy it leads to an unnecessary expenditure, hence a waste. In warehouses the loads are distributed in the same manner as in office buildings—full live-loads on beams, for they may receive it, but as there must be passage-ways to allow for the moving of goods the girders will only receive 80 or 90 per cent, according to the class of business.

There is a very good section in the Chicago Building Ordinance, that has been recommended by the writer for some years, requiring that there be displayed conspicuously on each floor of warehouses a placard stating the load per square foot of floor surface which may be safely applied to that particular floor, or in each particular locality should there be a variation.

The writer had occasion to estimate the actual loads carried in the dry-goods warehouses of Marshall Field & Co., in Chicago. The maximum load over limited areas was 57 lbs. per square foot, with passage-ways between for the trucks moving boxes of goods, so that the maximum average was less than 50 lbs.

The more storeys there are above any given column the greater will be the diminution of the live-load, hence, the reduction of live-load from the roof columns to the basement is justified by the facts.

With regard to the tile arches forming floors, experience has taught us that, all things considered, the most advantageous span between beams is about 6 feet. The longer the span the deeper the beams, hence the greater loss in clear heights of storeys, a matter of importance in Chicago, as the height of fireproof buildings is now limited by law to 130 feet from sidewalk to highest part of the roof. These hollow-tile floor-arches are laid in a strong Portland-cement mortar—one of cement to three of sand. The joints are entirely filled. To be assured of this, a special superintendent is put at the building. The tile are all inspected on their arrival at the building and any soft or imperfect tiles are discarded and immediately removed from the premises. Numerous tests of these floors have shown them to be in every respect satisfactory. A roller 6 feet in diameter with 16-inch face, weighing about 1,800 lbs., I have seen rolled over these arches before they were concreted. Obstacles such as brick, 2 inches by 4 inches scantling, &c., were placed before the roller and it was made to jump over them without the slightest effect on the arches. In one instance while we were making these tests a 12-inch I-beam, some 8 feet in length, fell three storeys, destroying a floor-beam in its fall by buckling the web, and struck on end on the top of the floor-arches beneath. It punched a hole through the top flange and fell over on its side, without otherwise disturbing the tile or injuring the soffit of the arch.

I note that Mr. Emperger speaks of the elastic limit of some steel at being below 30,000 lbs. per square inch. Such steel is not used in Chicago for constructional purposes, other than for rivets. Our specifications are those published by the Carnegie Steel Company in their "Pocket Companion," the edition of 1893, edited by Kindl, which calls for an ultimate of 60,000 to 68,000 lbs. per square inch, with an elastic limit of one-half of the ultimate. An examination of the test-sheets for the New York Life Building shows an elastic limit ranging from a minimum of 34,190 to a maximum of 38,380; the ultimate ranging from 61,190 to 67,850 lbs. per square inch. As we have a fibre stress of 16,000 we have a coefficient of safety of four.

Careful calculations are made for wind-pressure at 40 lbs. a square foot, and methods are provided to resist this pressure without exceeding the safety coefficient. Should a cyclone run the pressure higher, it would be but for a short time. As yet none of the steel skeleton constructions in Chicago have been in the slightest degree injured by the wind, although a cyclone about a year ago struck the Home Insurance Building, blowing some lights of plate-glass out of the sash.

These tall skeleton buildings, as they have been erected by the most experienced architects in Chicago, are designed and calculated with all the science, inspected and superintended with all the care and attention that is given to a railroad bridge of the first order, and we believe them to be fireproof, cyclone-proof and earthquake-proof. Certainly they have never shown the slightest signs of weakness under the severest tests to which they have been subjected.

CAERLEON AND ITS MUSEUM.

LIKE the Corinium Museum at Cirencester, this Monmouthshire museum, writes Mr. J. Ward, M.A., in the *Antiquary*, is exclusively antiquarian and essentially local. Most of its contents were found at different times in and immediately around the town, while a few relate to neighbouring villages, particularly Caerweni, about eight miles away. The residue came from more distant places, as London, York, Italy and Egypt; these, however, are treated as an illustrative series, precisely as in a similar class at Cirencester. For the above reason the collection cannot properly be studied apart from the locality, nor the locality from the collection—the one illustrates the other. Both, therefore, will be treated as equally essential to the present sketch.

When first I saw this ancient place, nearly two years ago, I was keenly disappointed. One is apt to presume that past importance is always linked with present vestiges of that importance. Think of Rome; it brings to mind ruined temples and aqueducts, early Christian churches and Mediæval palaces. How full of mementos of the past are York, Chester and Gloucester. But Caerleon, the capital of Britannia Secunda, the headquarters of one of the chief legions of the empire, an ancient archiepiscopal see and centre of learning, and the subject of many a Mediæval tradition and romance, surely of all places should be venerable with visible antiquity. But no; a passing stranger—even a lover of the past—might easily fail to discern in its narrow lanes, winding in a most un-Roman fashion, anything of more interest than is to be seen in most old-fashioned English village-towns. The huge mound or *burh* of the castle, on which probably stood “the prodigious high tower” of Gerald, the fine old, but over-much restored, Perpendicular church, with remnants of an early Norman structure, and some excellent examples of Tudor Domestic architecture, would undoubtedly attract his attention; but he would see in them only a proof of the post-Roman and Mediæval importance of Caerleon. Give him, however, but an inkling of the presence of Roman remains, and if his antiquarian perception is worth anything at all, he will not fail to trace the parallelogram of the castra from existing vestiges of the earth-mound and its masonry facing, nor to note the circular *cavea* of the amphitheatre, known popularly as King Arthur's Round Table. Were it not for the watchful interest of the Monmouthshire and Caerleon Antiquarian Association, these would probably now be the only visible remains of the Roman city. The numerous objects found year by year would either have received no notice or care at all, or, remaining in private hands, have gravitated to distant museums. But during the past forty or fifty years the little museum established here by this Association has been a successful means of gathering together and preserving finds. And now its varied contents, coupled with the remains *in situ* and the numerous records of past discoveries and investigations, furnish a by no means despicable knowledge of this important military centre of Roman Britain.

Historically, Roman Caerleon, Isca (the Latinised form of the river name, Usk) Silurum (to distinguish it from Damnonian), is little more than a blank. We may reasonably conclude that its importance to the Romans was an immediate consequence of the defeat of Caractacus, chief prince of Essyllwg, the land of the Silures. These hardy hillsmen, however, were never thoroughly subjugated, and their conquerors, like the Normans of a later age, erected a chain of strongholds to protect the fair lowlands of Gwent and Glamorgan from their attacks. These fortified stations were threaded by a great military road, the Via Juliana, stretching from Gloucester to St. David's Head, and the chief of these stations was Caerleon, the City of Legions. For a long period—probably two centuries—it was the headquarters of the Second Augustan Legion, and thus it played a part in respect to South Wales comparable with that of Chester, the headquarters of the Twentieth Legion, to North Wales. It is equally reasonable to believe—in fact, the existing vestiges clearly prove it—that as a legionary station it was a place of considerable splendour, however much we may feel inclined to discount Gerald's description. That we must take the words of this writer *cum grano salis* is proved by Henry of Huntingdon's statement of half a century earlier, which explicitly makes the walls so ruined as scarcely to be seen.

This contradiction will make us cautious with the statements of another old literary worthy, Geoffrey of Monmouth, who would have us to believe that Caerleon was founded by none less than the mythic Belenus, the conqueror of many nations and counterpart of the classic Apollo. From the same and other sources we learn that it was one of the three greatest cities of Britain, the capital of Essyllwg, and the birthplace of King Lucius. We tread on firmer ground in post-Roman times. This city was intimately connected with King Arthur, being the place where he is said to have been crowned and held his court. It is also the ecclesiastical mother of St. David's, whither the see was removed in the eleventh century.

Caerleon suffered much from the hands of the Saxons and the Danes, being several times burnt down to the ground; it

remained sufficiently important in even late Mediæval times to be incorporated. Its apparent destiny is to become an outlying suburb of the neighbouring progressive and rapidly-growing town of Newport, once the port of Caerlon.

The museum, which is so intimately connected with this most interesting place, occupies a conspicuous position near the church. It has the outward form of a miniature Classic temple, with internal dimensions of about 40 by 20 feet. Four Grecian Doric columns support a plain pediment, and behind them is the doorway, the only aperture of the walls, the interior being lighted from the roof. It is not a cheerful structure. These reproductions of Classic art in dull grey stone, and with our murky surroundings, are but parodies of the white marbles and the sunshine and pure blue skies of the Levant. The interior, however, has a good and even light, and thus so far is suitable for its purpose. The general construction distinctly recalls the atrium of a Roman house. The oblong central skylight would be a compluvium were it unglazed. The corresponding opening in the floor lacks water to make it an impluvium; it admits an uneven light into a dismal basement, or, nearer the truth, cellar.

There is no popular guide to the collection, and apparently no attempt is made to enlist the interest of the “common people.” I sounded several of the villagers as to their views on the museum. Let one suffice. She had once paid it a visit, but did not know what to make of the things. “They might be,” she assured me, “curiosities, but they ain't pretty.”

The impression the interior gives rise to is that the collection was once cared for, but has since been left to look after itself. The objects, as a rule, are accompanied by descriptive labels, but they are in a faded and dirty condition. There is a perceptible dampness pervading the room, which must be harmful to the exhibits; and to accentuate the “down-grade” appearance, the roof shows such ominous sign of collapse as to have recently necessitated a small forest of timbers to prop it up. In these respects this museum is a contrast to that of Cirencester, although so like it in others. Let it not be thought, however, that the scientific interests of the collection have been neglected.

During the forty-six years that the Association has been in existence it has published at irregular intervals various monographs and other works, and in these may be found described and illustrated nearly all the objects in the museum. The larger portion by far find a place in “Isca Silurum,” a careful and exhaustive royal 8vo catalogue, with 52 excellent lithographic plates. The author, the late Mr. John Edward Lee, F.S.A., a resident of the place, was long honorary secretary of the Association, and one of its most active promoters. This book was published in 1862, and is to a great extent a second edition of “Delineations of Roman Antiquities at Caerleon,” a work out of print at that date. In 1868 Mr. Lee published a supplement, dealing with subsequent additions to the collection. Since then nothing further has been done in this direction; but the few additions of late years have been noticed in ordinary publications of the Association.

VICTORIAN INSTITUTE OF ARCHITECTS.

THE annual report of the Council of the Royal Victorian Institute of Architects states that during the six months which have elapsed since their election the Council have held sixteen meetings. The stagnation in general business has been reflected in their proceedings, the greater portion of which have been necessarily devoted to the consideration of financial matters. Active steps have been taken to give effect to the articles of association in regard to obtaining payment of arrears of subscriptions. It is a matter for great regret that many members have found themselves completely unable to pay, and that in spite of the pressure exerted by the Council a substantial sum is still in arrears. The Council strongly sympathise with those individual members who are unavoidably prevented from paying, but in justice to the whole body of members they are compelled to insure, so far as is in their power, that all pay whatever their means admit. A proposal for affording a measure of relief to members, and at the same time for obtaining the earlier payment of current subscriptions, has been adopted by the Council.

One examination has been held during this term, but the candidates have been afforded by the examiner, with the sanction of the Council, a further opportunity of testing their proficiency.

The joint tenancy of the premises, just commenced at the time of the last annual meeting, has worked very satisfactorily so far. It is to be noted in this connection that a very sufficient test has proved that the necessity for keeping the reading-room constantly open up to 10 o'clock P.M. is not so great as was at first believed. The expense involved in doing this is therefore incurred no longer.

Certain alterations in the articles of association are thought ripe for discussion. The Council desire to record their best

thanks to those members who, either in committee, or as examiners, or as filling any other office, have supported them and carried out in detail the varied work of the Institute. They also thank the gentlemen who have contributed papers or addresses at general or sectional meetings, those to whose good offices are owing the opportunity of the various interesting visits which have been paid by members, and those bodies or individuals who have contributed to the library; and not least the press, for full and careful reports of the proceedings. During the time that has elapsed since the last annual meeting, the Institute has co-operated with other bodies in forming, under the auspices of the Chamber of Commerce, the "tribunal of voluntary arbitration" which has been officially inaugurated, though this method of adjusting differences has long been an essential part of the procedure in building operations, and is provided for with special care by the Institute.

The vigorous but necessary action taken, and to be taken, in regard to arrears of subscription will of course have the effect of procuring the retirement of those who can no longer afford the annual payment. A reduction in membership on this account may be looked for, and the Council would urge upon members the need for loyal and concerted activity in the interests of the profession through the medium of the Institute.

The social and literary committee report that since the holding of the last annual meeting the following visits have been arranged and successfully conducted:—To Messrs. J. Danks's Foundry, South Melbourne; the City of Melbourne Desiccator Works, at North Melbourne. During the last session four ordinary and three sectional meetings were held, at which the following valuable papers were read:—"The Melbourne Sewage Scheme," by Mr. W. Thwaites; "Australian Timbers," by Mr. Jas. Perrin; "Modern Drainage Principles and Practice," Parts I. and II., by Mr. A. M. Henderson; "The Advantages of Arbitration," by the president, Mr. Oakden, and Messrs. Billing and Inskip; "Architecture and Poetry," by Mr. E. W. Dobbs; "Architects and Electricity," by Mr. F. A. Fitts. A smoke night, in conjunction with the Institutes of Surveyors and Engineers, was held on September 12 to inaugurate the combination of the Institutes in one set of rooms, and proved successful.

THE EFFECT OF FROST ON GREEN MASONRY.

DURING the construction of the new theatre in Zurich, Switzerland, it became necessary to carry on part of the masonry during the winter. The contractors obtained advice from several sources as to the manner in which the work should be done, but as the recommendations were very diverse the Austrian Society of Engineers and Architects, which has made a special study of cements, limes and mortars, was asked to recommend a course of procedure. The matter was turned over to the cement committee, and this body instituted a series of experiments, which are described in the following free translation from the report in the Society's journal, and which appears in the *Engineering Record*.

The experiments were made in two ways; the first with brick masonry, and the second with rubble masonry, using stone of two kinds. This appeared desirable in order to determine if there was any difference between materials which were unlike hygroscopically. The materials used were dry and free from snow and ice, and the mortar was mixed as stiff as possible. The limes and cements were all tested in the municipal experimental station, according to the system of the Society.

The separate pieces of brick wall tested were about 3'28 feet long, 6'56 feet high and 12 inches thick, and were made with lime, Roman cement, Portland cement, mixed lime and Portland cement, and slag cement. The test walls made with these five mortars were laid with unwarmed water from the city mains and with water warmed to a temperature of 77 deg. Fahr. A series of tests was also made with Roman and Portland cements and cold water, to which 7 per cent. of its weight of cooking salt had been added. All mortars were made with one part of the cementing material and two parts of sand. In the mixed mortars twice as much lime as Portland cement was used. The lower half of the walls was partly protected by timbers, but the upper portion was entirely exposed. A few tests were also made with brick masonry laid with Hausleitner's frostproof Roman and Portland cements.

The test blocks of rubble masonry were 3'28 feet long, 6'56 feet high and 16 inches thick. The stone used was partly limestone and partly sandstone. These blocks were made with lime mortar, Roman cement mortar and Portland cement mortar, mixed with cold and hot water and cold brine as before.

The brick walls were started the last part of December, when the temperature was 26 deg. Fahr., and the fourteen pieces were finished in about three weeks. The temperature of the air was taken three times daily until the middle of April, the lowest temperature being on January 2, when 3 deg. above zero Fahr. was registered. The walls were pulled

down June 6. It was at once apparent that those pieces of masonry laid with mortar containing lime had suffered more from the frost in the exposed upper part than in the portions protected by timbering, since in the former the mortar had plainly been frozen. The following remarks give an idea of the condition of the walls, as revealed by an examination of the joints with a sharp iron.

1. Lime mortar mixed with cold water. The mortar in the joints had hardened but feebly, and the bricks could be pulled apart by hand without exercising any noticeable amount of strength.

2. Lime mortar mixed with warm water. The mortar in the joints had hardened feebly, and there was no adhesion between the bricks and the mortar.

3. Roman cement mortar mixed with cold water. The mortar in the outer and inner joints had hardened moderately, and there was considerable adhesion between the bricks and the mortar.

4. Roman cement mortar mixed with warm water. The joints were quite brittle and the inner portions of the mortar not particularly well hardened; the adhesion between the bricks and mortar was quite good. The part of the wall protected by timbers was in better condition and excelled any of the preceding walls.

5. Portland cement mortar with cold water. The joints were hard and the mortar clung well to the bricks. The protected part was better than the other in this case.

6. Portland cement mortar with warm water. The joints were hard, the mortar adhered well, and the entire piece of wall was a little better than any of the preceding.

7. Lime and Portland cement mortar mixed with cold water. The mortar was badly mixed, brittle and crumbling, but adhesive.

8. Lime and Portland cement mortar mixed with warm water. The mixture was uniform in this case, but the mortar was brittle and not well hardened in the interior, although adhesive.

9. "Frostproof" Roman cement mortar mixed with cold water. The mortar was well hardened, and there was a good adhesion between it and the bricks. A plaster of the same material, put on a part of the wall at the request of Herr Hausleitner, was thoroughly hard and without sign of injury.

10. "Frostproof" Roman cement mortar mixed with cold water. This mortar was well hardened, and adhered very well to the bricks. A plaster of the same material was thoroughly hard and without defects.

11. Wittkowitz slag cement mortar with cold water. The joints were brittle, and the mortar fell into little particles when scratched out with the iron. The inner parts, which had hardened somewhat, were crumbling, and showed but a slight adhesion to the bricks.

12. Wittkowitz slag cement mortar with warm water. The condition of this wall was but slightly better than of that last noted.

13. Roman cement mortar mixed with cold water, to which 7 per cent. of salt had been added. The mortar was brittle and crumbling, adhering but slightly to the bricks.

14. Portland cement mortar mixed with cold water, to which 7 per cent. of its weight of salt had been added. The mortar was well hardened throughout and adhered well to the bricks.

The masses of rubble masonry were built on a succeeding year, being started on December 28 and completed about two weeks later, the temperature ranging from 7 deg. to 25 deg. Fahr. The blocks were examined on April 7, and were found to be in the following condition:—

Limestone Rubble.—1. Lime mortar mixed with cold water. The mortar was completely frozen and brittle, without any adhesion to the stones. The block had fallen completely.

2. Lime mortar with warm water. The mortar was entirely frozen, brittle and without adhesion.

3. Roman cement mortar with cold water. The mortar had hardened pretty well, but had not the slightest adhesion to the stones, which could be removed from their beds without injuring the latter.

4. Roman cement mortar with warm water. The mortar was quite well hardened, but did not adhere in the slightest degree to the stones.

5. Roman cement mortar mixed with cold water and salt. In this block there was a partial adhesion between the stone and cement, and the latter had hardened somewhat better.

6. Portland cement mortar with cold water. The mortar had hardened very well and the adhesion between stones and mortar was quite good.

7. Portland cement mortar with warm water. The conditions were the same as with the last block, although the adhesion may have been a trifle greater.

8. Portland cement mortar mixed with cold water and salt. The mortar was very hard and adhered to the stones very well. The tearing down of the wall required considerable strength and necessitated the use of bars and other tools.

Sandstone Rubble.—1. Lime mortar with cold water. The

mortar was entirely frozen, brittle, easily broken, and without a trace of adhesion to the stones.

2. Lime mortar with warm water. The condition of this block was the same as that of the first.

3. Roman cement mortar with cold water. The joints were badly frozen, the mortar crumbling and slightly hardened. There was no regular adhesion between it and the stone.

4. Roman cement mortar mixed with warm water. This block was in the same condition as the last.

5. Roman cement mixed with cold water, to which salt had been added. The mortar was well hardened and adhered fairly to the stones.

6. Portland cement mortar with cold water. The mortar was well hardened, but its adhesion to the stones was only partly good.

7. Portland cement mortar with warm water. The conditions were much the same as in the last block.

8. Portland cement mortar mixed with cold water, to which salt had been added. The mortar had hardened very well and adhered firmly to the stones. The block could not be broken apart without tools.

The conclusions of the committee from these experiments are that in brick masonry laid in frosty weather mortars into which any part of lime enters should not be used. Roman cement mortars behave fairly well under such conditions, and Portland cement mortars give good results. The use of warm water gave somewhat better results, and salt materially increased the resistance to frost. With rubble masonry, using either sandstone or limestone, lime mortar was entirely out of place, and Roman cement mortar gave poor results unless mixed with salt. Portland cement mortar behaved well, especially with the addition of salt. The final recommendation of the committee is in laying brick or rubble masonry in winter to use only Portland cement mortar, mixed with salt if possible.

A similar subject was considered at a meeting of the American Society of Civil Engineers on March 7, when a paper by Mr. Cartwright descriptive of an electric station at Rochester was read. Colonel Craighill endorsed Mr. Cartwright's practice of soaking the bricks and salting the mortar in freezing weather. Mr. H. W. Brinckerhoff thought that the action of wet bricks and cement mortar would be very severe on the bricklayers' fingers, but Mr. Cartwright said that they were protected by rubber finger-tips, which he furnished by the gross.

Mr. B. R. Green thought that handling the bricks with the left hand exclusively, and the cement with a trowel in the right hand, the masons would not necessarily get any mortar on their fingers, but Mr. Cartwright explained that here the heart of the wall was filled with thin grout, in which the bricks were longitudinally rubbed along to a bearing and usually submerged. This made it impossible to lay them clean handed.

Mr. George Hill said that New York architects usually preferred to wait until warm weather to lay brick rather than do so with salted mortar and incur danger of more efflorescence. Here in New York he had cut into walls five or six months old that had been built with their centre courses flushed and rubbed down in stiff cement mortar, and had found the bricks and mortar inseparable and as hard and solid as stone. He knew of one brick wall where at a height of over 100 feet, with a south and east exposure, the efflorescence had reappeared annually for five or six years.

Mr. Cartwright said that it must have been due to some supply of moisture, and could be readily removed with a wash of dilute vinegar.

NATURE AND ART.

A LECTURE was delivered lately in Leeds by Mr. F. Suddards, of the Yorkshire College, on "The Influence of Nature on Art." In the course of it he said:—It has been said, with very much force and with a considerable amount of truth, that "all art is an imitation of nature." This must not, however, be construed too literally. Art is something more than a literal imitation of anything in nature, though there can be no doubt that it is so dependent on nature for its active life and development that it is impossible to separate the one from the other, and I purpose to bring before you the relation which there is, and has been, between nature and art, principally as it refers to the higher branches of painting and sculpture, but incidentally also as affecting the decorative and applied arts. A striking feature of the art of Oriental nations is that it has been nearly always stationary. In many parts of Asia, such as Persia and India, objects of great beauty, full of graceful design and glowing colours have been produced. Their treatment of nature is, as befits the decorative purposes to which their art is applied, very conventional, but it is also stereotyped and traditional, the productions of one age merely repeating those of former ages. Indian art, in common with Moresque, Persian, and the bulk of Oriental art, is distinguished by the compara-

tively slight reference which it has to nature; it never represents with any approach to truth a natural fact. For centuries it has been little more than a tradition; producing, it is true, many objects of beauty, but producing them without soul or energy. So long as the artist is content to simply go on repeating what has been done oftentimes before by his forefathers, and to rely upon traditional or purely imaginary forms, instead of going to nature for inspiration and guidance, progress or change will be conspicuous by its absence. In all branches of art workmanship, if there is to be any life or progress in it there must be the influence of nature constantly at work. A period in the history of art which offers a strong contrast to the traditional art of India, is that which in its highest development produced the great masterpieces of the Italian Renaissance. This great epoch embraces the period from the thirteenth to the sixteenth centuries, and has as its generally accepted founder Giotto, who lived and worked in the latter part of the fourteenth century. To understand the full value of his influence we must glance farther back, to the dark days of the centuries preceding. Between the fifth and the tenth century art in Italy had sunk to a very low ebb, and had become almost as stationary and traditional as that of the period to which I have just alluded. Early Christian and Mediæval art in Italy was characterised by its insipidity and formality, being little more than the ghost of the Classic, Byzantine and Mohammedan styles, or rather of a conglomeration of their styles, and containing neither the beauty of line and proportion or the marvellous knowledge of the human figure which belongs to Classic art, nor the skilful conventionality which was the peculiar quality of Mohammedan art. The Classic forms, so beautiful in the original, became stiff and cold, the figures became expressionless, and the draperies became wooden and unnatural—all this resulting from that easy-going tendency which led artists to merely copy the forms which tradition had handed down without understanding them, and to ignore the importance of that study of nature which was the basis of the success of Greek art. It was not until the twelfth and thirteenth centuries that art in Italy began to show signs of new life and vigour, and to lay the foundation of the Renaissance. The truth began to dawn upon the people that art, to be of any value whatever, must be a living reality, and this great truth received its first really great exponent in Giotto, whose life's work was the means of spreading the new gospel of nature in art to Italy and the world. In his wall-pictures (and nearly all his works were painted on walls), Giotto endeavoured to represent nature as he saw it, trying not only to get more truth in the representation of external forms and circumstances, but also aiming at giving the soul and character of his subjects, adding variety of expression where insipid monotony had hitherto existed, and giving description of incident where before none had been attempted. He boldly attacked subjects which had previously been either unthought of or had been considered impossible. Descriptive pictures of biblical scenes were a great advance on the old and stiff pictures of saints and angels, and instead of the flat, gold backgrounds of his predecessors, Giotto added perspective representation of architecture, which, though not perhaps scientifically accurate, helped to indicate the wonderful power which the study of nature was giving him to get clear away from the lifeless traditions of previous centuries. And not only was linear perspective attempted, but also the perspective of landscape and atmosphere. Crude and stiff they were, perhaps, but nevertheless a distinct advance on the usual gold background which had hitherto been in vogue. This great pioneer and his pupils were thus constantly opening the eyes of the people to the great and unfathomable beauties of nature. Art was still to a large extent the handmaid of religion, but not exclusively so, and various forces were helping to carry forward the movement begun by Giotto. The science of perspective was mastered; the anatomy of the human figure was made an important study among artists, and the invention of engraving in the fifteenth century also did something to help its progress, while a still more important impulse was the invention of oil-painting, which offered a medium possessing far greater scope for the realistic imitation of nature than any which had hitherto existed. All these forces were hurrying forward the time when the great masters of the Renaissance, Leonardo da Vinci, Michel Angelo and Titian, were to brighten the world by the splendour of their productions. By means of a series of typical examples which were shown on the screen, the lecturer then enabled his audience to realise the extent to which the study of nature had affected the progress of the period of art of which he had spoken. The names of Raphael, Leonardo da Vinci, Michel Angelo and Titian, he continued, are inseparably associated with this period, and in their works we see not only the highest perfection that had ever been reached in the technical side of painting, but also a combination of the highest forms of art with truth and consistency to nature. After dealing with the relation which the study of nature bears to modern art, a topic touched upon in his preceding lecture, Mr. Suddards continued:—With refer-

ence to the way in which art and nature are to be studied in relation to each other, it is possible that what I have said as to the relation of nature to art may lead some to think that mere imitation of nature is sufficient. If this were so all works of art of an ideal character would be bad, because they are not literal copies of some natural object or scene. A mere mirror-like rendering of whatever lies before us is not very high art, although for the purposes of the student it is a very necessary training. Art is something more than this, just as eloquence consists in something more than a merely accurate statement of facts. A portrait which is merely a soulless copy of the features of a man, without a hint of his character, is a poor thing. And so it is the interpretation of nature, not the literal imitation of it, which must constitute good art, and to the truthful observation of nature must be added the human feeling and authority in the manner in which it is interpreted. Even in landscape-painting, which is perhaps of all forms of pictorial art the one which lends itself most to literal imitation, artists are rarely content to copy nature without in some degree modifying their subject to suit their ideal. An examination of many pictures which seem to be nothing more than bits of natural scenery faithfully copied, and such pictures are often pleasing and acceptable, will show that the subject has not been copied with topographical accuracy. Objectionable features may have been omitted, the more beautiful parts may have been accentuated, and much depends on the selection of the most suitable condition of atmosphere and effect. A commonplace subject may under certain conditions look entirely beautiful; the artist may see charms of so subtle a character as to escape the notice of the ordinary observer, and his aim is to record nature in the aspect which seems to him most attractive rather than to paint a picture which will be at once recognised as being such and such a place. A landscape-painter does not feel flattered if he is told that his picture is almost as correct as a photograph, even though the critic may in the innocence of his heart intend it for a huge compliment. Photography has rendered immense service to art, but it is after all a science and not an art, though a science to which art can be applied. We all know the difference between photographs produced by a man with a knowledge of and feeling for what is artistically beautiful, and those produced by one who is totally without artistic feeling. The gap between them is great, but there is an even greater gap between photography and art. Here a further series of views taken, some from photographs and some from paintings, were thrown on the screen, and the lecturer explained to the audience how marked the contrast was between the two, stating with reference to a photograph of St. Hilda's Abbey and a painting of the same subject by Mr. Bernard Evans, which were in turn displayed, that the one reproduces every stone in the masonry, but the other gives the soul and poetry of the building as it rears its head to the heavenly light with which it is illumined. Art, he concluded, adds something to the natural beauty, but let us not forget that it is dependent for its healthy existence on nature. It is, as I have shown, a fact in history that as soon as art ceased to rely upon nature for guidance the result was decline and decay; but I would repeat that the true position of art to nature is not one of literal or photographic imitation; and if this can be realised, much misconception will be done away with and a higher appreciation of the more subtle beauties in art will be acquired.

SUSSEX ARCHÆOLOGICAL SOCIETY.

THE annual report of the Sussex Archaeological Society, which was read at Lewes, states that the past year had by no means proved uneventful from an antiquarian's point of view. The archaeological discoveries in Sussex, if not particularly numerous, included one "find," which in some respects might be regarded as the most important ever occurring in the county. This was the discovery of the Saxon cemetery at Goring, within the area of the camp on High Down Hill, which yielded a rich harvest of arms, ornaments and vessels, some being examples of a type not before known to occur in Sussex. A curious series of caves at Levant, found by accident, had been excavated and explored, and in Clayton and in Rotherfield churches mural paintings were uncovered, and, besides minor finds, the discovery of mural paintings upon an historic house at Pevensey, and of prehistoric remains at Eastbourne, had recently been reported to the hon. secretary. Although it was gratifying to receive these proofs that Sussex, long ago declared to be "worked out," still continued to furnish objects that excited the attention of every "student of the past," and also to know that in due course a record of these discoveries will appear in the volumes of the Society's "Collections," it was nevertheless with regret that the committee observed how few, comparatively speaking, of the portable antiquarian objects found in the course of each year were secured for the museum of the Sussex Archaeological Society, or for that of any similar institution in the county. In connection with this matter the committee invited suggestions

from members on the pressing question as to how the committee could best secure more adequate provision for the storing and effective exhibition of objects of art and rarity illustrative of Sussex archæology than was presented at Lewes Castle, which, though it had its attractive features as an historic and, in some respects, beautiful ruin, was not very well adapted for the purposes of a museum and library. The membership of the Society now stood at 656, and though a number of subscriptions were in arrears, there was a balance in hand of 52*l.* Details were given of the two days' tour in the summer around Chichester and Bosham. It was hoped that during the coming summer a start would be made with the publication of the Calendar of the Church Plate of Sussex and the Parish Registers, and it was intimated that nearly 30*l.* had been contributed towards the cost of excavations beneath Hastings Castle, in order to trace out a series of passages, supposed to be dungeons, and which appear to run in the direction of the Keep. The report and accounts were adopted. Horsham was chosen as the place for the summer meeting.

Cooper's Hill.

SIR,—The Italian work referred to in your notice of Mr. Francis, and ascribed to him, belongs to the additions made about 1872 by the late Sir Digby Wyatt, who converted the mansion built by Baron Grant into the Royal Indian College, and certainly doubled the original structure.—I am, yours obediently,

R. PHENÉ SPIERS.

Carlton Chambers, 12 Regent Street :

March 24.

GENERAL.

Sir P. Cunliffe-Owen, late director of the South Kensington Museum, died at Lowestoft on Friday in his sixty-sixth year.

The Glasgow Corporation are likely to purchase *Four Faggots*, by Mr. David Murray, A.R.A., the price being 400*l.*

Mr. Barber, C.E., of Silver Hill, St. Leonards, won the prize of 100*l.* offered for the best design for a new bridge over the Dee, costing 12,000*l.*

A Committee of the Edinburgh Town Council are to consider the advisability of forming a municipal collection of painting and sculpture, by purchase of works from exhibitions held in the city.

The Third Panel for the Ayr Burns statue, subscribed for by the Masonic lodges, is now completed. The subject is the "Jolly Beggars," and the sculptor is Mr. D. McGill, London. All the panels are expected to be placed in position by May.

Mr. E. J. Williams, architect, Bristol, has purchased Eagle House and grounds at Brislington, near Bristol, for a residence. The price was 4,130*l.*

Mr. Robert Gilmour has been appointed resident engineer to Greenock Water Trust, in room of Mr. James Wilson, who has removed to Edinburgh.

Mr. H. Green, of Norwich, has been successful in the competition for the Board school and master's house at Clench-warton, Norfolk. The design by Mr. H. Gibbons, of Westminster, was placed second. Sixty-four sets of plans were sent in.

Mr. J. M. Gray, the first curator of the Scottish National Portrait Gallery, died on the 22nd inst. in Edinburgh, after a week's illness. Mr. Gray was appointed about ten years ago. Since then he has arranged, classified and catalogued the collection of portraits.

A Cope which Mr. Bodley, A.R.A., designed, was presented to the Bishop of Lichfield on Tuesday. It is made of red stamped velvet, richly embroidered in gold. The orphery contains figures of six saints specially connected with the diocese, and the Annunciation forms the subject of the design of the hood. The morse is set with large carbuncles and amethysts.

The "Curfew Tower" at Barking will be restored if 500*l.* can be raised. The subscriptions amount to about 200*l.*

A Statue of John Howard, the philanthropist, by Mr. A. Gilbert, R.A., was unveiled in Bedford on Wednesday.

An Arts and Crafts Society has been started in Sheffield.

Mr. Thomas Helleyer, architect of the Royal National Hospital for Consumption, died on Saturday morning at Ryde, aged eighty-three years.

Mr. C. F. Binns will read a paper before the Society of Arts next Wednesday upon "The Elements of Beauty in Pottery."

A Post Office is about to be erected in Lichfield Street, Wolverhampton.

The Architect.

THE WEEK.

THERE never was a time when the demolition of ancient buildings caused so much regret as it does now in England, and yet they are being removed to an extent that is without precedent. It might be supposed that everybody is prepared to undergo sacrifices to preserve any building that is old; but when subscriptions for such a purpose are sought they are only to be obtained from a few. It is hard to expect that the owners of the buildings are to suffer unaided and to resist the changes which are demanded by the circumstances of the present age, or that architects should avoid any participation in those changes out of reverence for the work of their predecessors. If the public desire the preservation of old buildings it would be more becoming to agree to be taxed for that purpose than to be charging others with vandalism. But architects and antiquaries, if they are powerless to prevent destruction, can at least aid in preserving truthful records of the victims. Several efforts of the kind have been undertaken, the latest being exemplified in the drawings from the streets of the Metropolis which Mr. ROLAND W. PAUL has prepared and published at his own office under the expressive title "Vanishing London." The majority of the subjects are taken from Fleet Street, the Strand, and the streets adjoining that great highway. There are others from the eastern part of the City and some from Westminster. Altogether forty plates are given. Mr. PAUL draws like an architect—that is, he is careful in suggesting the character of all the elements of a building, and he does not evade the representation of detail by that more easy method of treatment which consists in making the building a subject for displaying contrasts of light and shade. It is not to be supposed that his style has the stiffness which is imparted by ruled lines; it is no less free from the irregularities which are believed to be a necessity of the picturesque. The drawings are exactly suited to become records of the buildings, and are therefore preferable to representations that might be considered as excelling them in pictorial effect. Most of the buildings are of the seventeenth and eighteenth centuries, and exhibit a restraint that is not always seen in provincial examples of the same period. Some examples have vanished since the drawings were taken, others are doomed to follow them; it is to be hoped that the buildings which occupy the sites will excite as much interest a century hence, or when their turn to disappear arrives.

THE collection of casts of Greek and Roman sculpture which filled a hall at South Kensington was brought together by the energy of Mr. W. COPLAND PERRY, the author of an excellent history of the art. Everybody who possessed a little acquaintance with the tactics of the department must have wondered to see an outsider exercising so much power. The reason was Mr. PERRY was able to persuade Lord SPENCER, the President of the Council, and while he was in office the officials were subjected to some sort of control. The casts were a valuable addition to the museum, especially as the collections are not rich in examples of Classic art. Mr. PERRY, we suppose, was happy in the thought that his casts would be more appreciated as years passed. He did not realise the jealousy which flourishes at South Kensington. At the end of last year he was alarmed to see some of the casts turned into a long dark gallery, but he was assured that tapestry was to be introduced to form backgrounds for the figures, and only a few of the casts were to be removed. On visiting the gallery a week or two ago, Mr. PERRY tells us how he "was struck dumb with astonishment to see that the whole collection, with the exception of the Parthenon and Phigaleian friezes—which look forlorn enough in their present surroundings, and which cannot be placed in the low dark gallery—had been swept out of the hall to make room for other things. . . . In fact, one can no longer speak of a Cast Museum in London. The

statues, collected with so much consideration and labour, have been contemptuously crowded out into a dismal corner, and a great and useful work practically annihilated." Mr. PERRY has received an unworthy recompense for so many years' toil, but he ought to remember that he is only one of the unofficial public and that he erred by anticipating official action. In the residences it is likely to be said that he should be grateful that even a dismal corner is allotted to his labour. No matter what the officials say, Mr. PERRY's fate is not encouraging to men who are desirous to increase the educational value of the museum.

IN Germany the liability of employers for accidents to workmen rests chiefly on the law of insurance, which dates from 1884. All employers are obliged to insure their work-people and clerical staff, even when the employment is temporary and unpaid. There are special associations for different industries, and the statutes must be approved by the Imperial Insurance Office. Injuries include those which are internal as well as external, loss of intellect, memory or nerve. When compensation is claimed, it is necessary to trace the injury to some specific cause, and not to the mere normal exercise of the occupation. Generally the person who is to gain or lose most by the undertaking is held to be the employer. Thus, in building contracts, it is not the capitalist who advances the funds, but the master builders, carpenters, &c., who are responsible. Employers' contributions to the associations are proportionate to their annual expenditure in wages. The amount of compensation is based on the wages received by the workmen during a year. So long as he is completely incapacitated, he is to be allowed two-thirds of his wages. For partial disablement he obtains a fraction of that maximum proportionate to the extent of the injury. In case of death, twenty days' payment (in no case a sum less than 30 marks) are to be granted towards funeral expenses. The widow, until her remarriage, is allowed about 20 per cent. of her husband's wages, whilst 15 per cent. is allowed for every child under fifteen who has lost one parent, and 20 per cent. if it has lost both. The total compensation to widow and children must not exceed 60 per cent. of the deceased's wages. In case of remarriage she receives as composition three times the amount of her annual allowance. If the deceased was the sole support of parents or grand-parents, they may receive 20 per cent. of his wages during their lifetime.

THE building trades show a rather large proportion of accidents. In 1888 the number of insured was 784,304 and there were 3,356 accidents, 584 being fatal and 410 causing total disablement. In 1892 (the last year for which there is a return) the insured numbered 946,702, while the accidents rose to 5,657; there were 694 deaths and 308 cases of total disablement. In most other trades the number of accidents was also increased. Various causes were assigned, among them being the division of labour and the abolition of the system of master, journeymen and apprentices. The building insurance associations ascribed the increase to the lack of technical knowledge displayed by the builders, and also to the undue concentration of workmen on the same spot, owing to the necessity of constructing buildings rapidly. In 1891 the sum of 7,665,150 marks was paid in compensation for accidents on buildings. The administration is also costly, amounting in 1892 to five millions of marks. It is acknowledged, however, that among all the social measures which followed the imperial message of 1884, the law of insurance against accidents appears to have been the most productive in good results. The successful working of the measure has been facilitated by the administrative machinery for military and police purposes. It has also been aided by the organisation of the old German guilds, and it is upon the guilds that the trades associations have been founded. Liberty has been left to the various trades to form their associations according to their own wishes. It was originally proposed to unite the industries of brick-making, potteries and quarrying into one association, but at the request of the trades three have been formed. In the same way it was intended to unite chimney-sweeping and building, but the sweeps preferred independence.

THE ARBITRATION CLAUSE IN AMERICA.

IT was often alleged by builders that they suffered inconvenience and loss by what is commonly known as the arbitration clause in contracts. At one time the conditions were of an absolute kind and in keeping with the rigorous spirit of legislation in general. The architect was accepted as being supreme in all disputes that arose. By degrees lawyers were able to obtain some modifications of the relations between architects and builders. As a consequence, in most modern English contracts provision is made for an appeal (especially on points in which the architect might be tempted to be biassed) to an arbitrator, who has had no share in designing or carrying out the works which gave rise to the dispute.

The change in spirit cannot be more clearly exemplified than by a comparison of contracts with the War Office, for they are likely to be inspired by discipline in its most rigorous form. It used to be the rule to give the commanding officer full authority in case of difference to purchase materials or to employ any men he might consider necessary. There was a saving clause which said:—"If at any time the contractor shall have reason to complain of undue or excessive severity in the conduct of the superintending officer, the contractor will, upon his representing the circumstance to the Board of Ordnance, have such proper redress as the honourable board shall find he is justly entitled to." A man could not have much experience in military works without having a misgiving that proper redress might take an unsatisfactory form. To some extent the same sort of saving clause is still in use, the Secretary for War taking the place of the Board of Ordnance; but it is also provided that "if so requested by the contractor, before giving his decision, the Secretary of State for War may appoint one or more competent persons, as he may think fit, to investigate and report upon the matters in dispute, the expense of such investigation being charged to the War Department or to the contractor, at the discretion of the said Secretary of State for War." This concession is almost equivalent to the clause proposed by the Builders' Association.

In the United States it would appear that the principle by which the architect becomes autocratic still prevails to a greater extent than in England. That at least is the conclusion that must be drawn from the proceedings of the Builders' Convention which was held in Boston on four days in February. The president, Mr. IRA G. HERSEY, declared the past year to be most disastrous, for the builders, in common with most men in business, could not escape from the general depression, but he considered they withstood the shock as well as the representatives of interests of similar magnitude. Among the events on which the President was able to congratulate the members was the increasing use of the approved "Uniform Contract," in which the arbitration of outside architects or specialists is recognised. On that subject he said:—

The method of arbitration recommended by this body is in more or less successful operation in several of our cities. The great obstacle to its universal adoption is the distrust that has been engendered by long lists of arbitrary acts. These are by no means confined to either side, but have been too commonly the weapons used as each in turn has felt they had the power to enforce their claims. In this respect there has undoubtedly been a steady growth of favourable opinion, until there is no fair-minded man who is not willing to accept the principle of arbitration as the fairest and wisest way of settling all misunderstandings. The wisdom of having these boards appointed in advance, before the heat of dispute has warped our judgment, is also, I think, unquestioned. But the benefit of having them in constant or frequent session is not so apparent, and has, in the absence of questions of importance to discuss, a tendency to magnify and distort minor issues until they become a disturbing influence and tend to defeat the very purpose for which the board was formed.

The Secretary, in his report, referred to an attack on the form of uniform contract by the Boston Society of Architects, but declared that the effect was to open the eyes of many people to its virtues. He recommended the discussion of the shortcomings to be undertaken in a temperate style; at the same time, he pointed out that all power to alter the conditions was vested in the joint committee of architects and builders.

Mr. J. S. STEPHENS, of Philadelphia, who is one of the committee on uniform contracts, was the first to explain

that the benefit which they expected to derive from the admission of arbitration was jeopardised:—

You remember, he said, that it was the universal custom, and is still the custom among some architects, to have inserted a clause in their contract that in case of a dispute the decision of the architect shall be final and binding. That was the one feature of the old contracts that we were most opposed to, and that we felt was the most unjust to the contractor, and in outlining our business with the first committee we laid down as a principle that the architect was the agent of the owner. We laboured a long, long while before we could impress upon the architects that that was a fact; we let everything else stand and bent all our efforts toward proving to them conclusively that the architect was the agent of the owner, and we had a vote on that subject, and it was agreed to. We felt then that we had some ground to stand upon, for as soon as it was settled that the architect was the agent of the owner, it wasn't much trouble for us to prove the manifest injustice of asking the agent of one party to decide differences between the two; our point was gained, and we were able to introduce this clause of arbitration. If you remember, in our contract it is stated that, in case arbitration be asked for, each party shall select one, and the two thus selected shall select a third, and their decision shall be binding.

It appears a case has lately occurred in Philadelphia which denotes that in spite of the resolution of the joint committee arbitration has not come into fashion. One of the parties to a building contract in which arbitration was agreed upon as a condition when a dispute arose declined to adopt that course of proceeding. The builder appealed to his lawyer, and was informed that the recalcitrant party was acting within his rights. Other lawyers were consulted, and came to the same conclusion. It was found that the decisions in the Supreme Court of Philadelphia made it necessary that not only the principle of arbitration should be recognised in the conditions of contract, but the names of the contemplated arbitrators should be introduced in the deed. The Act 52 & 53 Vic. c. 49, known as the Arbitration Act, provides against an evasion of that sort, for it says, "In this Act, unless a contrary intention appears, submission means a written agreement to submit present or future differences to arbitration, *whether an arbitrator is named therein or not.*" English decisions are received with respect in the American Courts (and *vice versa*), but a definition in an Act has not the same claims to attention. It is hard on builders to have their contract deeds nullified at the pleasure of people who may wish to avoid paying debts, but it is only by that sort of experience that laws are brought into a workable condition.

Another speaker, who contended that more of the disputes which necessitate arbitration arise out of defective drawings and specifications than out of questions of price, offered some strange revelations about American working drawings. He said:—

I find that I get a set of plans with a line of cornice, say, shown on them, and I frequently find that there is nothing in my specifications or plans to tell me whether it is iron, stone, metal, or what it is. I frequently find that in an elevator shaft walls are shown without any foundation plans shown for them. Now, my experience is that my disagreements arise not so much on variation as to price, but as to the work to be done. It frequently happens, and it has happened to me many times, that I refuse to do work under a contract, and the architect claims, under the specifications that take in almost everything in this world, that it is in my contract, and I have got to do it. Now, what I claim is that the uniform contract has provided for no means of arbitration except upon two points—first, as to the price of extra work; and second, as to the damages for delay. I have to-day a disagreement on a contract where I have a few thousand dollars coming to me, and the architect, although I have got a uniform contract in that case, absolutely refuses to arbitrate, or the owner refuses to arbitrate, and I do not know of any means of making him. Now, of course, we all agree that it is very essential and that it is very fair and proper that we should have some clause of arbitration. I have in mind one case I have tried to arbitrate, where I have 15,000 dols. or 16,000 dols. involved. That building has been occupied since March 1893, and it will take me, I presume, at least three years to get any action on that at all; in other words, I am kept out of my money by arbitration longer than it would take me to get it before a Court. Of course there is something monumentally unfair about that.

It would be preferable if in the cases mentioned the architect had been accepted as the sole arbitrator. There may, however, be many architects in America who are disposed to interpret conditions literally, and in that way give trouble. A case of the kind was brought before the Convention. There is a clause in the uniform contract which says:—"The contractor, under the direction and to the satisfaction of the owner and architect, must complete the work." It is not happily expressed, but still it is sufficient to prevent the settlement of an account without much

reason. In the case in question the contractor, after fixing some of the steam heat radiators which are common in America, painted and gilded the pipes. But it was impossible to apply gold in the narrow spaces between the pipes. The architect, it appears, was theoretical rather than practical, and he said the work was not finished according to his satisfaction. The owner, who happened to be impetuous, was also dissatisfied, and the consequence is the contractor remains unpaid. What is more, he appears to have no remedy, and the model form of contract is not of much service to him. An example of that kind suggests that "'cuteness" has not ceased to be a characteristic of the States.

Builder and building owner may agree to arbitration, but another obstacle has to be overcome, viz. the appointment of an umpire. The secretary of the Convention related how he acted as one of the arbitrators in a case where from 75,000 dols. to 80,000 dols. were at stake. The building owner's lawyer said there was no need to appoint an umpire at once, as the arbitrators could proceed until differences arose. The proceedings were carried on for two or three weeks, then, as apparently was expected, there was a dispute between the lawyers and arbitrators about prices, which made the existence of an umpire a necessity. Then came another contest about the selection of the third judge, which was ended by the abandonment of the inquiry.

The law's delay has also to be considered. One of the builders read a letter from his lawyer, who informed him that as the Courts were far behind in their work, it was impossible to reach the first stage in the trial of an action in which he was concerned under two or two and a half years. Afterwards it might be necessary to go through the Appellate Court and the Supreme Court of the State. The lawyer observed how "it is a difficult matter to keep track of a score of witnesses for two or three years, in order that they can give testimony on the merits of a case that may be tried at that time, and may not be tried for a year or two later." The costliness of the action naturally bears a proportion to the difficulty.

It is an old belief that in a multitude of councillors there is safety, and American builders appear to believe they will receive more justice from three referees than from one architect. They would do well to remember what one of their countrymen said about power educating the potentate. From having to decide judicially, English architects have something of the equitableness and impartiality of those who wear ermine in the Courts. In dealing with differences they could not be described as agents of the owners, although in law they have to act as such at other times. If the American architects were as much trusted it is not unlikely they would save builders from the waste of money and loss of time and peace which uniform contracts cannot prevent.

F. WALKER AND J. W. NORTH.

AN exhibition of works by the late Frederick Walker and Mr. J. W. North, A.R.A., has been arranged in the rooms of the Birmingham Society of Artists. On Thursday in last week the president, Mr. Herkomer, R.A., delivered an address on the characteristics of the two painters. He asked what could be more wholesome for students than to see their pictures, and what was more likely to stay the wave that was passing over English art just now—the mad striving for originality at all cost? There they had two eminently sane artists, neither striving after originality, but both accomplishing it by dint of their own idiosyncrasies, developed by earnest attention to nature. There they saw not only sweet nature represented, but sweet English nature, for the tenderest note in English nature had been struck in both—true, noble and pure nature, free from all taint of eccentricity, free from all desire to excite surprise, and yet free from all tediousness. The art practised by both men belonged to the best side of every man and woman who loved England. It was a natural art, evolved out of the resources nearest at hand, and this constituted in it an element of greatness. Not the least interesting point about it was that it was more or less an outcome of the feeling for nature fostered by wood-draftsmen, for both men started as such. Both were apprenticed to an engraver to draw, not engrave, on wood. But some time before Walker began to paint North was doing little water-colour drawings from nature, when he went into the country and managed by some art means or other to get his living since he was sixteen years of age. In those early drawings North's

identity might be plainly visible. Walker, always the better draughtsman and man of larger scope, was long before he could shake off the trammels of black-and-white work, so that his early work was rather hard and cold in colour. It was principally through the companionship with North that Walker merged into the colourist, which found its highest expression in *The Fish Shop*. In this drawing Walker reached not only his highest manipulative aims, but the highest possibilities of the material. It was a triumph to have reached such perfect harmony between detail and breadth, between colour and tone, between drawing and sentiment. As he would call Millais's picture of *The Carpenter's Shop* the pivot upon which English art turned, so would he call *The Fish Shop* the climax of English water-colour art. Perhaps if Millais's picture had not been, *The Fish Shop* would not have been possible. The search for truth did not stop with Millais. But truth to nature took a particular artistic form in Walker, which culminated in this identical drawing. Both North and Walker started a truer daylight aspect in their wood drawings, and Walker was the first to represent the light of England's grey sky—not one of those foggy somethings—that magical light which gave each object in nature its full value, both as to form and colour, and yet gave mystery to parts that were only needed to balance the composition. The lay audience would forgive him if he addressed himself more particularly to students. The Walker school had right aims in their work, and although both men were before his (Professor Herkomer's) time by a decade, there was in his time still a striving to make all illustrated work pictorial, and all pictures illustrations of true scenes in nature. This gave the illustrator a chance of touching subjects that he could afterwards render in colour in a more complete form. *The Vagrants* was first drawn on the block and afterwards painted. With this practice of making black-and-white pictures the painter's hand showed a cunning not to be obtained merely by the practice of painting. He doubted if either of these painters would have seen nature just in this peculiar way if they had not been illustrators in black and white first. Literally the power of illustration would mean the highest gift in the artist, because it would not only mean the possession of the power to represent nature truly, but would include the illustration of the man himself. In this way Watts was pre-eminently an illustrator of poetic and abstract ideas, which he repeated in artistic language, thus satisfying the painter as well as the poet. The theory of "self" in art was one little understood, but its potentiality was unmistakable. To be without identity was to be without "self." But they must beware of mistaking this for mere mannerism, which was only a habit of work. That could be carried further into dramatic art. It was Irving's strong theory that people went to see Irving's view of different characters. He (Professor Herkomer) said that was right. A man so to lose himself in a character that he was absolutely somebody else meant that he had not the power to illustrate the subject from his own point of view. It was the illustrator that they wanted, not merely the man who could disguise himself. Irving said "any fool can disguise himself." This particular "self" developed differently in different people, and he maintained that a certain training would, in spite of all natural bias, bring about a somewhat similar result. But no training had left so strong a mark upon the painter as the one pursued by Walker and his followers. It consisted of a transition from the illustrator in black and white to the water-colourist, and from thence to the oil-colour painter. No academical training could give the character to a man's work that was obtained in this way, which practically meant training whilst producing serious work. Therefore, it followed that this school was made up of what the world called "untaught" or self-taught men. Their secret of success lay in "going on" with the subject, with the assistance of nature, until it was right. This same training was followed by Adolph Menzel, whose work was distinctly in accord with the category under discussion. His colour alone differed from English feeling for colour, partly because he had been born and bred in a different atmosphere. He was first a lithographer, then a wood-draughtsman, then he painted in water-colours and finally in oils. There was a danger in taking to the more robust medium last, and he knew to his cost what it took him to become a "comfortable" oil-painter. E. J. Gregory said to this day that he was more comfortable in the use of water-colours. North said the same, although nothing could be more truly an oil-picture, with all the robustness the material was capable of, than the superb landscape of his they had lately added to the permanent collection in the Art Gallery. It would amuse them to know that this very picture was North's first oil-picture, begun twenty years ago, and he (Professor Herkomer) took a little credit upon himself for having forced him to finish it last year. The Walker school had a further invaluable lesson to teach the modern student, namely, it was not fragmentary, it was not empty of subject or of thought, because the aim of these painters was to make a picture of everything they did. This he had from the lips of E. J. Pinwell, and he had it from Walker. These men were the very opposite of clever sketchers.

Whenever they left off in a work, however slight, it was an unfinished picture and not a complete sketch. If there were students there he could not urge this virtue too strongly upon them. And to the art-loving section of his audience he would say this lesson was equally valuable, for they must know the difference between a sketch—which went no further and which could not be carried further—and a work which had set every fibre of the artist's brain in motion. The latter might be done in an apparently slight manner, but there was meaning in it impossible to attain in the other form. Speaking of wood-draftsmen of the present day, he said the age tended towards fragmentary work. The telegraphic form of expression found its way into letters—it was the Triple-Bill Age—which was in such a hurry that it could not read an article of a column in length unless it was divided into innumerable little paragraphs, each with a sensational heading. Here they had two painters whose works were entirely removed from the pressure of haste. In Walker they had the Botticelli of our time, and in North they had a gentle poet who ought always to help them understand the real beauties of English landscape. In Walker they had the modern Renaissance truly exemplified. And surely it was more profitable to see beauty in peasant-life than only its grim and ugly side—its "faceless" side. They might admire to the full the big dignity the French Millet gave his work, but he never once painted the face of a peasant. Strangely enough there was one aspect of nature that brought Walker in one example very near to Millet's self, and that was in *The Mushroom Gatherers*. The treatment of that was directed by the demands of the effect. Having so completely changed his method of work when the subject required it, they could once and for all absolve Walker from mannerism. Another curious and debatable point in Walker's art was his miniaturesque treatment of faces in the midst of more vigorous work. In the larger oil-picture of *The Plough*, the faces of the boy and the man were positively miniatures. Art became sadly interrupted when they saw a picture painted with the same rigid touch from the top of the sky to the edge of the foreground. That was the most modern tendency. Therefore in Walker they might still feel that the faces thus manipulated held their place in the general effect when they looked at the picture from a distance, and on closer inspection their more critical faculties would receive the additional joy in the beauty and finish of any particular face. If this finish interrupted the general effect of the picture it would be wrong, but if its application in no way interfered with breadth it was an additional quality greatly to be admired. In the *Old Gate* could be noted the intense finish produced with the point of the brush in the face of the labourer, yet the top of the hand was roughly done, imperfectly it might be said, and that came near the face. This apparent want of harmony in the workmanship was justifiable from the painter's point of view, because it emphasised that particular grey-day effect, and Walker must have felt this. Never before or since had that effect been more truly represented than in the *Old Gate*. It was painted in the companionship with North; indeed it was North who found him the background which suggested the subject. Touching upon the classical beauty of the male figure, he pointed out that some people suggested that English labourers should not be done like Greek gods. He wished to settle that question of Anglo-Greek gods in disguise once and for all. He would say that the English labourer was as finely built a person of that class as they could find in the whole world, but they must see him without his clothes—they must see him when he was bathing. Without their clothes they were superb, they moved like Greek gods. But put on their clothes and they partook of their sphere of life at once. If therefore the Greek god was under the clothes, Walker was surely justified in showing that fact through the clothes. That was what he complained of in the French Millet—that everything should be so awkward and clumsy. Probably the most complete of the oil-pictures was the *Harbour of Refuge*, now, he was thankful to say, given to the nation by Mr. Agnew. Here they had a superb water-colour drawing of the same subject. The human interest in the picture was full of pathos. There was striking contrast in the figures without, however, the slightest buffoonery. There was an exquisite balance in the composition of the whole picture, and it was absolutely removed from the mere book illustrations. However beautiful *The Vagrants* might be in the National Gallery, he still felt it to partake too much of the black-and-white illustration, done for a certain purpose to a given size. In the *Harbour of Refuge* they had all the training of the illustrator brought into beautiful harmony with the more or less accepted rules of composition. They would note the transition from the use of body-colour to that of pure water-colours. Walker's drawing of *The First Swallow* was thickly painted with Chinese white. It was not a question of the durability nor of the legitimacy—this use of the white—they must judge it from the pictorial side entirely. And here the taste of the artist must be considered. Many tones were producible with white that could not be produced without it. It was a lovely drawing, but if they looked at the distant trees

it would be seen that he had attempted to do a difficult thing in nature with impossible means. He alluded to the light coming through the trees. The dots of white would never give the effect. He must, however, remind them that the use of white generally facilitated drawing, and any one trained in black-and-white work would naturally take to it as a medium of great usefulness. In the *Philip in Church* they could see the use of it. Walker was the founder of a peculiar line in his black-and-white work—a gradated line, fine at the ends and broader often in the centre, mostly done with a brush. From his time to the present there had been three remarkable lines produced by three different men in black-and-white work, viz. Walker's gradated line, Charles Keen's split line, and Phil May's line, for which he could find no name. Phil May had produced a line that had the charm of the finest etched line, yet it was palpably a pen line, but so wondrously used that it was unapproachable, as they could see by the numerous failures of his imitators. Walker's line hardly suggested colour as much as Keen's, but it was robust and eminently picturesque. The three lines should be carefully studied by all students, for they told the history of our times. Finally, he urged them all to become students whilst they had this rare collection before them; not merely allow their taste to guide them, but try and understand what the two remarkable painters intended them to see in nature. Let them, he concluded, be led by the hand, and they would be the happier for the lessons thus gained.

WEDGWOOD AS A POTTER.

THE prizes obtained by the students of the Tunstall School of Art were handed to them by Sir Richard Temple, M.P. In his address he said that, should it appear presumptuous to them that he, a busy politician, should address them on art, he might say that he had himself practised the pictorial art all his life. In addressing them upon art, he recognised the fact that he was standing in one of the great art centres of England and in the very heart of the Potteries, those ceramic institutions that had conducted to the fame of England in the world. He wished to impress upon them that a master potter must of all things be an artist. He must be very much of a chemist, much of a mineralogist, something of a mechanic, something of a botanist, but above and beyond all these things he must be an artist. If he were not, then, in spite of all his great qualifications, scientific and otherwise, he would never be qualified to inherit the conditions of the great master potters of England of the last century; he would never be qualified to be a successor of those who made Worcester, Burslem, Etruria, Sèvres and Dresden what they had been and what they still were. They might be thankful that, despite certain disadvantages, they could produce some of the most splendid specimens of ceramic art to be found in the world—things made not in the last century but to-day. On the previous day he had seen at Worcester specimens of Oriental figures which represented the plastic art in its very highest forms; but of all the artists we ever had in the plastic line in England he placed foremost of all Josiah Wedgwood. That day he had made a pilgrimage to Etruria, and he could understand the veneration which clung to the spot, to the workshops, to the mansion and to the tenements where the great master potter and his colleagues once worked, and where his successors were trying to emulate his work. Wedgwood was an Englishman of the truest type—practical above all things, inquiring, investigating, contemplating, executing, and, though a man of humble education, yet he managed to acquire a degree of taste and culture which had rarely been surpassed in the annals of this country. He gathered round him colleagues who supplemented all those qualities in which he himself was defective. He had the good sense to take Bentley into partnership, while he employed the great artist Flaxman as designer, just as Messrs. Minton now employed their distinguished fellow-citizen, as he might term him, Mr. Solon. And they should remember that had there been no Wedgwood, perhaps we might not have had a Flaxman. It was Wedgwood who sent Flaxman to Rome and sustained him there, who induced Bentley to visit France and sent his own accomplished son on an artistic mission to Germany. And if his Staffordshire friends had sometimes heard it said that Wedgwood himself did not invent and did not design, but entered into the thoughts and labours of others, they should not allow that for a moment to detract from his merits as a whole. After all, it was the genius which collected materials from various sources that gathered up the threads of other men's thoughts, that collected the dry bones of experience and that clothed them with life and animation. When it came to be inquired into, the great plays of Shakespeare and the poems of Homer would be found to be based on well-known legends of the time, and through the whole range of genius, ancient and modern, every individual who had left his mark on the human mind began to collect his materials in the same way as Wedgwood employed his artistic and industrial life. But it was in his power of adaptation of means to the end, of execution

and of administration, of getting things done in a grand, original and purely artistic manner that the great fame of Wedgwood prevailed. If the canons of art as illustrated by Wedgwood appeared to militate against the present practice, they must attribute that not to the potters themselves but to the public taste. He was only lamenting the previous day at Worcester the change which had come over much of the noble porcelain manufacture there, and he was told (and it might be true) that they could make anything, but they had to adapt themselves to the public taste on both sides of the Atlantic. It was clear then that it was the public taste which must be educated. Wedgwood, towards the end of his life, when he was making his work more and more beautiful, found that his most lovely specimens remained on his hands. They would not be taken into the market in consequence of the deficiencies of public opinion and taste. Now, surely the first point in every work of art was that it must be beautiful. That appeared a truism. Were any quite sure that the production of beauty was the object of every work in art, whether in plastic or sculpture, or any other art? He apprehended that very often artists tried to produce something wonderful, thinking of the astonishment they created rather than the emulation they evoked. The first object always before the mind of Wedgwood and men of his class was the production of beauty. If there was to be beauty they must in the first place have breadth and simplicity; these two things were conspicuous in the works of Wedgwood. He (Sir Richard Temple) had his own library, as old as Queen Elizabeth's time, chiefly ornamented with wood-carvings and a few specimens of old Wedgwood ware. These plaques were the admiration of everyone who entered the room. And why? Because there was simplicity of form, breadth of design, and the true gentility of sentiment. The subjects were classical, adapted to the requirements of English art of the last century. But there was that beautiful breadth and simplicity which were always found in the works of great artists, and were rarely found in the works of inferior ones. Were they sure that breadth and simplicity were always preserved in modern works of art? Look abroad in domestic ornamentation—look at architecture on both sides the Channel—was not the form, the outline, the design constantly overlaid by masses of detail, both of form and colour, which might be lovely enough if taken bit by bit, but by which the whole effect was lost when they contemplated the work as a whole? That was the first great canon with regard to which Wedgwood differed from the present generation, and it was for them to say which was right. He did not hesitate to say he was for Wedgwood. There was another great point, which was that the work must have character. A flat surface was level, so was detail level; but they must be co-operative, they could not have all detail or all flat surface. They must have enough of each, so that each should have its separate character. That cardinal point was invariably to be observed in the works of Wedgwood; and he left it to their impartial judgment if they went through Regent Street or Bond Street to say if this was a characteristic observable at the present day. So much for ornamentation. All these qualities that he had mentioned to them came into the general phrase ornamentation. But in this ornamentation there were two main divisions—one of form and one of colour. As regarded form, there must be curving; all fine works of art must have a curve. Ruskin would go so far as to say every line in nature, even comparatively straight lines, appeared to be curved. No man understood this more perfectly than Wedgwood. There was not only the curve, but that swelling proportion which never failed to delight the eye. But when they went to form they had to think of two great divisions—first, the forms of nature; secondly, the human form. As regarded the forms of nature, no one ever observed them more accurately than Wedgwood. As he roamed about Staffordshire and the sylvan environments of that day, he never failed to keep his eye fixed upon the foliage of trees, the petals and leaves of flowers, besides the natural bloom. In his eye there was a sort of dreamy perception of everything lovely in the works in the creation. That was as it should be. Floral decoration took such a part in pottery that a man must be something of a botanist if he was to attain to the highest excellence of plastic art. The potter and the pottery artist worked in two capacities. There were men who only painted; and another gentleman would undertake sculpture; but a master potter must be efficient in both. In that respect no class of artist had to be so comprehensive and world-wide in his thought and capacity as the master potter. In the human form, Wedgwood showed his wonderful perception. His (Sir Richard's) theory was that Wedgwood and men like him perceived that they could not master the human form in action in this humid climate, for the reason that persons were always clothed. No nationality ever acquired the power of the ancient Greeks and Romans in representing human forms. When people knew that their breasts and busts and arms and shoulders were constantly seen, they got into the habit of standing and moving gracefully. They would be surprised if they could see the figures

of the peasant girls of any part of India, because they were uncovered to the waist and held the pitchers above the head. That induced people to move about in that graceful manner, and gave the best models to the sculptor. This was understood by Wedgwood, and therefore he got his best models from Classic times. Now as to colour, there was a quality in colour difficult to describe in words. Nowadays they produced a certain quality in a very simple manner by having all the colours harmonise, because none were anything in particular. A taste was coming into vogue of having all the colours creamy—he would not say wishy-washy, but would call it *impasto*, which meant the same thing. Delicate creams, delicate pinks, imperceptible greens, tender yellows, delicate orange did produce harmony, but that was not the great object of colour, the perception of which Ruskin declared to be the noblest gift of God to man. Colour was splendid, deep, rich. He would not say that was perfectly perceived by Wedgwood, but it was partially perceived by him, and it was nobly perceived by Worcester men of the early part of the century. But Wedgwood did perceive this—that to have a blue they must have a deep blue like the violet blue of the starlit heavens. Besides colour there must be light and shade, and that no doubt came from the variegated surfaces of pottery to a certain extent. Further than this, there was the sense of proportion. If there were a want of proportion, they might have a most graceful outline, the most complete forms, the loveliest details, yet if proportion were wanting the work would be defective, and as the sum total of all these qualities there was this one which artists called composition: that composition was the grouping, so that there might be a pervading effect, a prevailing character throughout the same work. A master potter, to follow in the footsteps of Wedgwood, must understand composition. Lastly, there must be usefulness. Recollect, if they examined the finest works of art in almost all branches in the world, they would find the most beautiful works subserve some useful purpose. He recollected amongst the many admirable things said by Mr. Gladstone, when speaking on Wedgwood, he said Wedgwood's ware was perfectly useful, was convenient, was adapted for practical purposes to a degree unknown to the master potters of that period. There must be a pervading sentiment—a sentiment of beauty, gracefulness, elevation, adaptability, suitability, convenience and usefulness all round. In conclusion, he would say to them, as Staffordshire people, they were living in one of the great art centres of England and of Europe. They were the men and women who by their nimble fingers, their trained eye, their cultivated minds had rendered the name of English potters famous in the world and everywhere victorious against all competitors. That was a great honour, preserved for their children and their children's children by constant study of nature, of all examples which the Creator of the universe had set before their eyes.

ROMAN BOUNDARIES IN BRITAIN.

A PAPER by Dr. Hodgkin on "The Limes Germanicus: Discoveries in Germany as to the Manner of Marking the Roman Boundary," was read at the last monthly meeting of the Newcastle Society of Antiquaries. The author stated that the boundary was concealed from the general observation, and the line of frontier was discoverable at need. Trees were planted to give a general indication of the line of boundary. It remained to be seen what result this discovery in Germany would have on the excavations which he trusted the Newcastle Society of Antiquaries would resume this summer on the Northumberland Roman Wall and Vallum. He quoted from a letter from General von Zarwey, who suggested that a similar boundary should be searched for in Northumberland, and who thought that the society should look for the boundary forward of the southern line (the Vallum?) and to the ditch of the murus. If the hypothesis of Professor Haverfield were right, he (the General) thought that the southern line was the original political limit, and it was probable that this limit was marked out by meerstones. It was difficult to say where these were to be sought—certainly on the northern side of the fosse, perhaps under the mound thrown out on the side. The society would best attain their object by making sections at right angles to the course of the Wall, but he (the General) also thought that they should also extend their researches to the Northern line of Hadrian's Wall. The Newcastle Society would perceive that the great difficulty in reasoning by analogy from the German Limes to their own lay in the existence of the Vallum. If it were the boundary between Roman and Barbarian, Hadrian's Wall, unlike the German Limes, was built upon land lying outside of the strict limits of the Empire. All discussions about the Wall, Dr. Hodgkin said, led them to the external question as to the object of the Vallum. Let them hope that the stout arms of some of the Northumbrian peasants might help to solve this question for them before 1894 expired.—The chairman, Canon Greenwell, said he could not entertain

for a moment the idea that the Roman works in Northumberland were works to show the limit of the Empire. They were works of defence.

TESSERÆ.

Types of Venus.

THE Greek religion was the religion of the imagination, and each of its divinities embraced a poetic conception. Foremost among these was Aphrodite, the representative of purely material life, and whose attributes were consequently selected in this connection, as those of a more subtle and spiritual were grouped around the rare and mysterious Psyche. Out of the flashing foam of the Ægean, the finest expression of its bright and sparkling life, the starry grace of childhood arrested, and united with the winning tenderness of the woman, the blushing Aphrodite comes smilingly forth to greet the hoary Earth. Of all the expressions of this idea which the Greek sculptors have left us, and which are still preserved to us in the Italian galleries, the Venus de Medici is perhaps the most famous. That the figure is very beautiful it is impossible to deny, but as it is a beauty which grows upon the beholder, the first impression in most cases is one of disappointment. Much of its peculiar charm, moreover, is due to its small and delicate proportions. In its fairy-like grace and size it resembles the Undine of the German tale, but it is Undine when she has exchanged the mere lovely infantile instinct for the true woman life, for the complete understanding of the nature she has gained. Upon the whole, however, and to the ordinary student of art, the Venus of the Capitol is perhaps as popular as any—not undeservedly so. An ocean shell is woven into the gathered hair, which in wavy ripples is braided low down upon the brow—"as low as she could wish it," like Octavia's; the face is characterised by a mild, dreamy, refined intelligence, and the attitude, though perfectly feminine, is queenly and impressive. It is not, perhaps, so perfect and elaborate in some of those details of execution to which the scientific anatomist attaches so much importance, but certainly as a charming representation of the rich and perfected beauty of a woman, it is more completely satisfactory than the other. The gathering of the drapery around the feet of the Venus known as the Venus of Praxiteles is remarkably effective; and the sweet, grave, sightless beauty of this stained and mutilated copy yet serves to account for the unrivalled fascination of the Cnidian Aphrodite. Contrasted with the Greek idea of Aphrodite is that of Athena—wise, chaste, severe, inflexible.

Shrines in English Churches.

The shrine of Edward the Confessor, in Westminster Abbey, will serve to illustrate the arrangement of Becket's shrine, and probably those of the other principal saints. It stands, like Becket's, in a chapel, and separated from the choir and high altar by a reredos, but yet not a detached building, as the lady chapels so commonly were. Architecturally speaking, the chapels of Becket and Edward are within the choir at its east end; the pavement in both cases is raised above the level of the choir, and each shrine is a parallelogram on the plan, and stands east and west. The altar is at its west end and in contact with it, so that the saint is placed behind the altar, *retro altare*; and reciprocally, the altar is at "the head of the saint," since the head of a corpse was always laid to the west. These phrases have already occurred in quotations from the monkish chroniclers; for example, in the Saxon cathedral the matutinal altar was placed at the head of Dunstan, and Anselm, Odo, Wilfrid and others were deposited behind altars. On the other hand, in chantry chapels the tomb of the uncanonised founder is commonly at the west of the altar, so that the priest stands at the foot of the tomb. The description of the shrine of St. Cuthbert, at Durham, will also serve to illustrate the two already mentioned. This, too, was placed behind the great reredos of the high altar upon a raised platform enclosed, and forming what was called a "feretory," or chapel for the reception of the feretrum. This platform may still be seen extending partly into the great eastern transept, or "Nine Altars," as it is called. In the midst of it "his sacred shrine was exalted with most curious workmanship of fine and costly green marble, all lined and gilt with gold, having four seats or places convenient underneath the shrine for the pilgrims or lame men setting on their knees to lean and rest on, in the time of their devout offerings and fervent prayers to God and holy St. Cuthbert, for his miraculous relief and succour." Under the shrine of Edward the Confessor there are arches, three on each side, which probably served for a similar purpose. "At the west end of the shrine of St. Cuthbert was a little altar adjoined to it, for mass to be said only on the great and holy feast of St. Cuthbert's Day in Lent. . . . And at this feast, and certain other festival days, in time of Divine service, they were accustomed to draw up the cover of St. Cuthbert's shrine, being of wainscot . . . and a strong rope was fastened thereto, and did run up and down in a pulley under the vault for the

drawing up of the cover; fine sounding silver bells were fastened to the said rope, which at the drawing up of the cover made such a goodly sound that it stirred all the people's hearts within the church," &c. This cover was painted and varnished within and without; and within the feretory, on both north and south sides, there were ambries of fine wainscot for relics.

The Statue of Athena on the Acropolis.

There is enough to show that the Greek was entirely free from modern prejudices, whether for or against decoration by colour. The mingling of stone or marble, or of marbles of different colours, the introduction of metallic ornaments on statuary or works in relief, all subserved this purpose, not less than the employment of polychrome; and even without the use of a single pigment, the sculptor was enabled to produce works not less gorgeous than the painter. Formed of materials altogether more facile and malleable, the chryso-elephantine statue gave (what modern sculpture has not so much as aimed at), the living hues of the human form and the varying tints of embroidered garments. With the most sumptuous of these statues is associated the immortal name of Phidias; but the works themselves have perished. The colossal statue of Athena was plundered of its golden raiment by Lachares, and finally transported by order of Justinian to adorn the Hippodrome of Byzantium, whither that of the Olympian Zeus had been conveyed before. The restoration, therefore, of these statues must depend on the statements of writers like Pausanias, together with any designs on stone or metal which may chance to throw light upon it. At the Paris Exposition of 1855 was exhibited a restoration of the Athena of Phidias (on a smaller scale) by M. Simart, who had chiefly followed the Vienna stone with the name of Aspasius subscribed. This remarkable work was executed at the cost of the Duc de Luynes, whose liberal patronage and exquisite taste suggested this revival of one of the most famous works of antiquity. In spite, however, of the vast expenditure lavished on this chryso-elephantine statue, the effect it produced was scarcely equal to the idea generally conceived of the Athenian goddess; and a controversy arose as to the accuracy of the representation. From the expressions of Pausanias M. Beulé inferred a complete absence of all ornamentation, except on those parts of the statue which were nearest to the spectator, thus confirming his own theory of the uniform simplicity and extreme severity of the art of Phidias. The contrary ideal furnished by the sculptured stone of Aspasius he rejected on the ground that the lunated sigma, in the inscription, was not employed in Greece till the second century of the Christian era, and the work was therefore not produced in the golden age of Greek art. M. de Calonne asserted that the name may possibly be the forgery of a later age, and he produced several inscriptions to prove that the lunated sigma occurs as early as a century and a half before the Christian era, and that it was not a Roman introduction. If then the Vienna stone represents the Athena of the Parthenon, it must belong to the best epoch of art, because it must have been executed before the statue of Phidias was robbed of its ornaments; and if it be of that epoch, can it possibly represent any other type than that which Phidias evoked, and which was everywhere regarded as a miracle of beauty? But the ideal set forth in this stone is that of extreme richness over the whole figure; and, after all, the expressions of Pausanias scarcely justify M. Beulé in using them as negative arguments. Because Pausanias says nothing of the crest of her helmet, of a collar or earrings, are we to deny that they were found on the statue of Phidias? Nor has M. Beulé less exposed his weakness in maintaining that the Medusa of the shield was represented as a monster only in the decay of art, while that of Phidias was "a beautiful young girl with dying eyes and immobile lips." If this be so, Attic art in the days of Pericles grievously violated all the traditions of earlier ages. The glaring eyes of a maiden lovely even in death can never be the sight which could appal the warrior amid the din of battle, or freeze a living man into stone.

Verulam House.

When Chancellor, Bacon had built a summer-house about a mile from St. Albans, near the famous Byzantine ponds. The Gothic pile enlarged by Sir Nicholas for Lady Anne, which had come into his possession on his brother's death, stood high and dry above the water, and as the stream would not flow up to his house, he took his house down to the stream. Avenues of stately trees sloped from the hall door to the little lakes, which, four or five acres in extent, were kept bright as crystal, filled with brilliant fish and paved with pebbles of various hues. On the bank of one of these lakelets he had built Verulam House, a tiny but enchanted palace, one front leaning on the water, the other glancing, under oak and elm, up the long leafy arcade to his mother's house. This place was furnished and complete. The larders and kitchens were underground; through the centre of the block ran a staircase delicately carved; on the rests and landings a series of figures—a bishop, a friar, a king, and the like, not one repeated either in idea or

in execution; on the door of the upper storey statues of Jupiter, Apollo and the round of gods. Beauty and luxury combined were chimneypieces prettily wrought, rooms lofty and wainscotted, baths, oratories, divans. Shafts from the chimneys ran round the rooms, with cushions on these shafts, so as to garner up the heat. The roof, which was flat and leaded in the Eastern manner, commanded views of wood and water, plain and upland, with the square plain Saxon tower of St. Albans Abbey high above all. In the centre pond rose a Roman temple or banqueting-room, paved with black and white marble. One of the doors had a device of mirrors, so that a stranger fancied he was looking into the gardens when the door was closed.

The Perspective Process.

On first learning the meaning of a picture, it would naturally strike the mind that a sure and easy method of carrying any point from its position in space to its position in the picture would give any one the power of drawing the outline required. Such a process might be laborious, but it would put the whole design within possible reach. This method would be an excellent one for learners to begin with, previously to entering on the use of vanishing points; it would be something like learning to count with pebbles before entering on the common rules of arithmetic. Even without diagrams it may be possible to give such a description of the process as will enable some who have never attempted anything before to put a few simple figures into perspective. Let the picture plane, which suppose transparent, be spread out before the spectator, reaching down to the ground, and bounded on the right by a side-wall, which extends both before and behind it. Every point which is to be drawn has a point directly below it on the ground, which call its ground-point; and a point directly opposite on the side-wall, which call its side-point. All the ground-points make, when properly joined, what the architect calls a plan; all the side-points an elevation. The picture would be called a section if points were taken on it opposite to the points to be represented; instead of this a point is carried to its place on the picture along a line drawn to a certain point in front of the picture, which represents the eye of the spectator. This eye-point has also its ground-point and its side-point. The picture has its ground-line and its side-line, and every point in the picture has its ground-point upon the ground-line and its side-point upon the side-line. A picture-point is known when we know where the ground-point is by its distance from the side-line, and where the side-point is by its distance from the ground-line. To lay down a given point on the picture, draw a line from its ground-point to the ground-point of the eye; that line meets the ground-line of the picture in the ground-point of the picture-point required. In the last sentence for ground read side, and we see how to find the side-point of the picture-point in the side-line of the picture. Two lines being drawn on a paper perpendicular to one another, the right side of the paper may represent the side-wall laid flat on the ground by turning round its ground-line, and the left side may represent the ground-plane. The two sides of the line which separates the upper part of the paper from the lower represent the ground-line and side-line of the picture. Take another paper, or another part of the same paper, draw two perpendicular lines, lay down the ground and side picture-points by taking their distances from the paper on which they have been found, and the points of the picture may at once be put in their places. This is an explanation of the principle of a picture and an exhibition of a sufficient method of construction; that is, of sufficient power, but not of sufficient facility; every point requires the drawing of three lines.

Florentine Portraiture.

The people of Florence, devoted to commerce, had been steadily advancing in wealth and importance; the arts were patronised by her chief merchants, not for mere historic association, but for the benefit and gratification which they so readily afford to those who best cultivate them. They were thus enabled to honour the memory and perpetuate the personal appearance of their most illustrious citizens. Hence portraiture, an important and comparatively a novel feature in modern Italian art, attained an especial preference among the Florentines. The dramatic and thoroughly independent tendency of Giotto's conceptions illustrates this. Dante, Petrarck, Boccaccio, Cimabue, Donati, Brunetto Latini, Bettino di Bardi, Dello and Michelozzo were only a few of the distinguished persons depicted by the earlier Tuscan artists. This natural desire to honour great men nurtured the faculty of imitation, and attained at last so wonderful an approximation to reality that this very power took afterwards a somewhat pernicious tendency. Not that accuracy of imitation could in itself be injurious, but danger arose from the painter's liability to make a successful imitation the sole end and object of his work. Hence, not merely in pictures belonging to the second half of the fifteenth century, and professedly of a strictly religious

tendency, might the features of a well-known living person be recognised, but occasionally the lineaments also of those whose morals were frequently questionable; thus the serious impressiveness of the picture would be impaired, and the work deprived of that devotional character which ought to have pervaded it. By too implicitly copying the realities of everyday life, the very action, or as the Germans would say, the motives of the picture are radically disturbed, and simpering Madonnas, angels in extravagant attitudes, and martyrs looking to the spectator, in consciousness of his presence, for sympathy, are only one small portion of the mischiefs which may be traced from the perverted use—not only in painting but in sculpture also—of servile imitation.

Modern Architecture.

In all countries of the world down nearly to the present day, and in Europe down to the sixteenth century, architecture continued to be practised, and everywhere with success, on the same principles as in all ages governed, and do still govern, the development of all the sister useful or technic arts. At the Reformation a new and extraneous principle of imitation was superadded, and for the last three centuries we have been labouring under the delusion that it was neither science that advanced the art nor truth that rendered its production pleasing, but some strange notion that it would be beautiful if it could only be made to look like something it was not, or had only some very slender connection with. What is now wanted to restore the art to its pristine pre-eminence is a return to those simple principles which guided the architects of Egypt, India, Greece, Rome or the Middle Ages, and which are identical with those that now guide our shipbuilders or machine or engine makers, or the engineers who construct our bridges or our forts. There is absolutely no mystery about it. All that is required is strict and undivided attention, first, to convenience, next to constructive necessities, then to the ornamental or harmonious arrangement of the parts, and lastly, when it can be done, to their ornamentation. It may require more thought and self-negation to succeed by this path in the present state of the art than by following the fashion of servile copying; but by the one path certain success may be easily and permanently obtained by even the most moderate abilities, while by the other path no genius will enable any man to erect a building which will be considered successful many years after its completion. This may appear a daring assertion, but it is justified by the experience of 4,000 years, during which the first path was followed by all the nations of the earth with uniform success, and by the experience of the last 400 years, during which the other process has been cultivated, and anyone is able to judge how far during it men have succeeded in attaining what they sought for. Taking into consideration the amount of money spent, the amount of talent employed and the amount of knowledge available, the result has been the most complete and lamentable failure in the artistic history of the world.

Volume in Art.

It has long been said that in nature nothing is absolutely small, nothing is absolutely large; but whenever we see a new object we are led to compare it with that which we know to be analogous to it, and it is then large, if its size or volume markedly exceeds that of the object with which we compare it; volume becomes a property which strikes us in proportion to that difference. Of two statues or two busts representing the same model but differing in size, the largest, though of equal merit, will strike us more than the other. But we must not omit to remark that if we are accustomed for a certain time to see only statues and busts which both surpass the human proportions, then the influence of volume loses its force; and moreover, it may happen that after having seen many of these works, constructed so to speak on the same colossal scale, and having less merit than the work that struck us at first, we should be disposed to recur to figures life-size. But if the volume of an object has undoubted influence in striking spectators forcibly, we must never forget the inconveniences that result from exaggerating a single object which ought to be associated with others; for in this case the exaggeration may have the serious objection of lessening these latter, and thus breaking the harmony they would otherwise possess.

The "Standard" Correspondent in Athens announces that the French excavating party at Delphi have discovered a fine head of an ancient statue of *Apollo* belonging to the classical period. Several interesting inscriptions have also been found on various antique bronze objects, which are in a good state of preservation. The American School of Archaeology in Athens has solicited permission from the Government to excavate the foot of the lower parts of the North Acropolis, and is prepared to spend half a million francs for this purpose.

NOTES AND COMMENTS.

THE difficulty which often arises about fixing responsibility on landed proprietors for negligence was exemplified a few days ago at a coroner's inquest held in Wavertree, Liverpool. A slater who was walking along an open pathway in the evening diverged from it in the dark, and, falling into an unprotected quarry about 80 feet deep, was killed. At the inquest one of the solicitors for the Heathfield estate stated that his firm, as representatives of the owners, were ordered by the local board to build a wall at the point where the accident had occurred. They appealed against the decision, and on March 21 Mr. Justice CAVE decided the case in their favour, and the order was quashed. It was pointed out to his lordship that the owner of the quarry could not fence the place, as he had no land to build upon, whereupon his lordship said that if the local board could not find a proper responsible person to do it they would have to remedy the defect themselves. The clerk to the Wavertree Local Board said that they had no right to build a wall at this place, as the land on which it would have to be erected belongs to the Heathfield estate, and they would be trespassing. The coroner said it was really disgraceful to leave the place in such a condition. It seemed to him that the owners of the land could not be called upon to build the wall unless it was proved that there was some obligation made as to fencing. They might summon the lord of the manor, the Marquis of SALISBURY. It seemed to him, from the reading of the Quarries Act of 1875, that the quarry was a nuisance, as it was within fifty yards of a public highway, and it was not fenced, and therefore the owner of the quarry ought apparently to be liable. The clerk asked how this could be done, as the owner of the quarry had no land to build the wall upon. A fence at the bottom of the quarry would not be of any use. The coroner said it was desirable to do something at once. The owners of the land, the owner of the quarry, and the local board might come to some arrangement and contribute equally to the cost of the work. The jury returned a verdict of accidental death, adding that proceedings ought to be taken for the erection of some barrier by the responsible persons.

THE statue of JOHN HOWARD which has been erected in Bedford is not, of course, the first representation of the prison reformer. There is another by BACON in St. Paul's. HOWARD, if he desired, might have had his statue during his lifetime. When he was suffering from fever in a Turkish lazaretto he received the news that subscriptions were being raised to pay for a memorial of that kind. As soon as he returned to England he lost no time in publicly announcing his repugnance to the proposal. The money obtained for the statue was returned to the subscribers, some of whom expended their shares in the liberation of poor debtors from gaol. HOWARD died in Cherson among the Tartars in 1790. When the intelligence was received the project of a statue was immediately revived. Opportunity was taken of the occasion by the Marquis of LANSDOWNE to offer suggestions about public monuments. His proposals were:—1. To reserve St. Paul's, the second building in Europe and the first in Great Britain, from being disfigured or misapplied in the manner of Westminster Abbey. 2. To assist the arts most essentially by advancing statuary, which may be considered as the first, because it is the most durable among them. 3. To commence a selection of characters, which can alone answer the purpose of rewarding past or exciting future virtues, and the want of which selection makes a public monument scarcely any compliment. The selection might be made subject, in the first instance:—1. To the King's Sign Manual. 2. The vote of either House of Parliament. 3. The vote of the East India Company. 4. The ballot of the Royal Society. 5. The sense of any profession, taken under such regulations as may be deemed most unexceptionable. 6. The same as to artists, men of letters, or other descriptions, subject to proper regulations. The subscription and the vote must be a sufficient check upon all the latter description. Upon the same reasoning, some spot might be reserved for eminent foreigners, who are very properly, while living, associated to the Royal Society and

other learned bodies. But none ought to be admitted in consequence of the wish or sole opinion of families or individuals. It might, perhaps, be thought proper to leave it to the Royal Academy to form a general plan, and they might class the several descriptions, allotting places to each." It is probable that the restrictions adopted by the Dean and Chapter were due to Lord LANSDOWNE's recommendations. Although opinions may differ about the fitness of some of the statues, it must be acknowledged that in St. Paul's there is an absence of the memorials of nonentities which disfigure the walls of Westminster Abbey, and which, sooner or later, may cause the building to be transformed, in order that similar hospitality can be exercised by the authorities.

IT will be observed from the copy printed on another page that the rules of the Education Office do not correspond with those issued last year. The system of teaching has become an important factor, and it is no longer sufficient to mention the number of children for whom accommodation is to be provided. It is recommended that "before instructing an architect, the teaching staff of a school should be well considered, so that the number of rooms and the accommodation of each may be approximately settled before the expense of building is incurred." A normal class-room is one which is "wide enough to allow the teacher to stand at such a convenient distance from the front row of desks that he can command the whole class; and, on the other hand, only so wide that his voice may reach the scholars in the back row distinctly without undue strain." Four rows of long desks and five rows of dual desks are sufficient. If only one class is taught in a room the depth of the class may be increased. In large schools more than one entrance to each department is considered desirable instead of one to each school. Every part and corner of a school is now to be fully lighted, and it is added that "large spaces between the window-heads and the ceiling are productive of foul rooms." By a new rule "windows should be carried up as nearly to the ceiling as possible." As regards ventilation, it is prescribed that "an outlet should have motive power by heat or exhaust." The allowance for outlets is to be $1\frac{1}{2}$ superficial inches per child, and rather more for inlets. For passages or corridors used by boys or girls there must be complete supervision from class-rooms by sheets of clear glass. Where cesspools and privies have to be used, they must be at least 20 feet from the school, and the proximity of drinking-wells is to be carefully avoided. A covered marching ground is considered to be desirable in the playground. An open fire was required in the infants' room, but now it can be warmed in another way provided the temperature is maintained at about 65 degrees. A bonnet room will have to be provided near the cookery class-room.

THE investigations of the Vicomte G. d'AVENAL have produced several remarkable facts about the variations in the value of land in Paris. It appears that in 1380 the Hôtel Dieu possessed a field which extended from about the Rue Chaussée d'Antin to the Rue Scribe. The Opera House, Grand Hôtel and Vaudeville Theatre are now upon it. At that time the rent was 200 francs a year. In 1399 the rent had fallen to 135 francs, and in 1472 to 37 francs. In 1533 the rent was 39 francs, but the area had been increased by another piece of land which extended to the Madeleine, the whole property comprising an area of four acres. As the annual value was only about forty francs, the property at fifteen years' purchase would be worth 600 francs. In 1552 the value was 1,900 francs. Two hundred years afterwards the value rose to 25,400 francs; in 1767 it was 64,000 francs, and in 1775 it became 260,000 francs. The ground which in the time of FRANCIS I. was let at 40 francs is to-day worth more than forty millions of francs. The increase has been as 1 : 66,666. It is not to be supposed that in all Paris a corresponding variation of value could be traced. In the sixteenth century the field was in the country; to-day it is the centre of Paris life, to which strangers no less than natives are attracted.

ILLUSTRATIONS.

FIGURE FROM ALTAR-PIECE, STOURBRIDGE.

WE give to-day another figure from Mr. L. FAIRFAX-MÜCKLEY'S wall decoration in a Stourbridge church. It will be observed that the type adopted differs from that of the figure published last week, but is no less suitable for the subject.

MENTMORE, BEDS., FROM THE GARDENS.

LORDSHIP LANE HALL, S.E.

THIS hall provides seating accommodation for about 370 people, and has cost 3,500/. By means of colours effect has been gained which cannot be suggested in the drawing. Luton bricks with red dressings have been used for the dado, malms above bays only being finished in plaster-work. The object of the two levels for the floor was to fit the hall for use for private purposes, the top floor being for refreshments and a lounge, the lower for dancing, and in this it has been found particularly successful, as also that the finish gives a warm and furnished appearance, without special decoration. The architect is Mr. H. G. BRACE.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening, Mr. A. W. Earle, member of the committee, in the chair.

London Streets and Buildings Bill, 1894.

Mr. F. T. W. GOLDSMITH, hon. secretary, introduced the subject by reading the petition of the Association against the Bill, and also notes on the subject, which were as follows:—

These few notes, hastily put together at the suggestion of our worthy President, are limited principally to the various amendments and additions to the Bill which appeared in the report of the general committee to the London County Council, and subsequently in the petition of the Association against the Bill now before Parliament. When I explain that these notes were written during the Easter holidays, and at very short notice, I feel sure I shall have an indulgent audience, and one that will be kindly disposed to the many defects discernible throughout these notes. They are to be taken as illustrative of the work done by the special sub-committee appointed to consider and report on this measure.

The London County Council forwarded copies of the Bill to the Association, with a request that we should consider and report to them upon it, not with regard to the principles of the Bill, but more particularly with reference to amendments to the text.

What the sub-committee did was to deal with such parts of the Bill as were distinctly structural and involving serious amendments and alterations to property within the sphere of the Bill.

The Architectural Association is, I believe, the only Society that has petitioned against the carrying up of the party wall above the roofs of buildings of the dwelling-house class. Mr. Carøe's letter to *Architectural Association Notes* this month will have brought this before the notice of members, and the views expressed in his letter have been duly set forth in our petition against the Bill.

The general grounds of opposition to the Bill, as stated in the petition, are that it "contains clauses which would be impracticable and inoperative, and in many instances the operation of the Bill would involve great loss to owners in the Metropolis, without any compensation to them or resultant benefit to the community in general"; further, that the provisions of the Bill injuriously affect the recognised rights, interests and privileges of the petitioners.

The petition then enumerates the main defects of the Bill, as already reported to the London County Council. These I propose to give—omitting only some minor amendments to the text—in the order found in the report and petition, adding a few remarks on the suggested alterations. Amongst numerous undesirable provisions to be found in the Bill are the frequent references to the option of the Council. These permits should not be allowed; nor, indeed, should they be necessary in a measure of this kind. If any references are to be made, let them be to the new tribunal of appeal; those to the County Council, which are so plentifully scattered throughout the Bill, should be eliminated. That is the first recommendation. This tribunal of appeal should commend itself to the favour of us as architects, though perhaps we would welcome an addition to the architectural and artistic element on the tribunal, even though it were at the cost of the existing preponderating officialism.

Part I., section 13, may be taken as a sample of a confiscatory clause—there are many such in the body of the Bill—where, if a fire were to occur in a building, the owner of such building would not only be a loser by the casualty, but would be a sufferer in having to set his building back to the line of frontage

required by the Council. Section 14 might be considered confiscatory.

Part II., section 15.—Where buildings are situated on corner sites this section should only apply to a new site.

Section 17.—This clause should be put at the end of Part II., and made to apply to the whole part.

Part IV.—This has been the great battle-ground of advocates and opponents of the Bill, and it is probable—if the Bill should ever be referred to a committee for serious consideration—that on the sections of this part there will be some good hard hitting. The general opinion is that, as drafted, the part is absolutely impracticable, and that it must go root and branch. "There are," our report states, "serious objections to the whole part. It is quite unworkable in its present form, and should be entirely remodelled."

Part V.—The rules in section 39 should be definite, not subject to any alterations or by-laws. Here follow certain verbal amendments to the text which I will not trouble you with. There is one alteration, however, which is important; it is in section 43, where after "as follows" is added, "or such other scantlings as may be approved by the district surveyor." Attention is called to the obscurity of section 45. Under this section, apparently, a person might, by surreptitiously erecting a water-closet or other small building against his neighbour's wall, actually convert the whole into a party-wall.

All chimneys should be corbelled only above the ground floor, for chimneys corbelled in accordance with this section would cause the walls to overhang.

Now we have arrived at a truly burning question. Should the party walls of dwelling-houses be carried up above the level of the roof? Mr. Carøe has been kind enough to hand me a paper he has prepared on this and other points, with a request that I would read it at this meeting, which I propose to do.

It is proposed to insert after section 45 the following words:—"Every party wall of any new building, being a dwelling-house (as hereafter defined), and every party wall of any such old building shall be carried up to the roof of such building throughout the entire length of such wall, and the slates or other roof-covering shall be properly and solidly bedded in mortar or cement upon the top of the wall, and the roof shall be so constructed that no timber or woodwork of any description shall extend upon or across any such wall."

And section 46 of Part V. should read as follows:—"Every party wall of any building of the warehouse class, or of any public building, or building used wholly or principally for purposes of trade, shall be carried up above the roof flat or gutter of the highest building adjoining thereto to such height as will give a distance (in a building of the warehouse class) of at least 3 feet 6 inches, and (in any other building as referred to in this sub-section) of 15 inches above the highest part of any flat or gutter, as the case may be."

Of the artistic gain to London streets and terraces, if these clauses were adopted, there can be no doubt. Mr. Carøe is prepared with evidence on the practical question of protection from fire, and does not rest his contention for this change on any fanciful or sentimental grounds. I now propose to read the amendments suggested in the report and petition from section 50 to section 60, which I would specially mention:—

Section 50.—(6) Add "render" outside of flues where brickwork is less than 8½ inches in thickness, except where it forms external enclosure of the building.

Section 50.—(10) "Mantel" to be altered to "lintel" or "arch."

Section 50.—(15) Alter to "6 inches wider on either side than the width of the opening."

Section 50.—(22) Add "no iron girder to be placed nearer than 4 inches to the inside of any flue."

Section 51.—Add new section "that perforated iron cresting at the top of chimney-shafts should not be allowed," as iron decays and is difficult to repair.

Section 52.—(5) Define "low pressure."

Section 53 should be redrafted. It is not comprehensible at present.

Section 55.—(b) 7 feet 6 inches instead of 8 feet 6 inches.

Section 55.—(d) Impracticable and impossible throughout.

Section 55 (f), line 15.—After "floor" add "except when constructed of fireproof materials."

Section 55 (f), line 16.—Add after "quality" or "fibrous plaster of a good quality."

Section 56.—Add "window or" and "skylight or" before "windows" and "skylights."

Section 57.—After "10 feet" add "except the lift in wells of staircases."

Section 58.—(1) Rise of arch should be stated, minimum 1 inch to the foot.

Section 60.—(2) I will not ask you to picture to yourselves London as it would look if every cornice—however deep or what its position—were limited to the projection prescribed by this section.

It is proposed to omit clause b in section 60 altogether, and

in section 61 after "materials" (line 8) to add, "and separate sets of offices tenanted by or constructed, or adapted to be tenanted by different persons, shall, if contained in a building exceeding 25 squares in area, be separated from each other where they adjoin horizontally by proper party structures or arches of fire-resisting materials."

Section 64 is slightly amended, but section 65 (4) and (5) the term reported would be wholly inoperative.

Part VII.—Section 72 (3) is ambiguous, and sub-section (6) unfair to the adjoining owner. The building owner could put footings to his new wall into the adjoining owner's room, if on that level. This the latter might reasonably object to, and it is proposed that after "owner" (line 21) should be added "below the level of the lowest floor line."

There would seem to be nothing in this Bill binding the building owner to pay for any necessary underpinning or other works to the adjoining wall. Section 75 deals with the "exercise of rights by building and adjoining owners," and the appointment of surveyors in case of disputes arising. The report states that the arrangements made under the 1855 Building Act have been found to work well, and there is no need to alter such arrangements as is suggested to be done by this section of the "London Streets and Buildings Bill, 1894."

Section 80 is slightly altered, being amended to include underpinning and the cost of doing the same.

The sub-committee would not have section 184 at any price, and the report and petition contain this clause as redrafted by the committee. In its amended form it reads, "With the exceptions mentioned in this Act, this Act shall apply to all new buildings. Any alteration, addition, or structural reinstatement made or done for any purpose except that of necessary repair not affecting the construction of any external or party wall, or to which the rules and regulations of this Act are inapplicable, in, to, or upon any old building, or in, to, or upon any new building after the roof has been covered in, shall, to the extent of such alteration, addition, or work, be subject to the regulations of this Act; and whenever mention is hereinafter made of any alteration, addition, or work in, to, or upon any building, it shall, unless the contrary appears from the context, be deemed to imply an alteration, addition, or work to which this Act applies."

The petition concludes with the customary formal clauses that the Bill should not be read a second time, but that if it is to proceed, it ought to be referred to a committee of the House, and that the petitioners should be heard before such committee by their counsel, agents, and witnesses against the principle and details of the measure. If the Bill be read a second time, the petitioners pray that it may be referred to a committee of the House, as before, with counsel, &c., and that such other relief may be afforded to them (the petitioners) in the premises as to the House may seem meet. The petition was signed by the President, two Vice-Presidents and the hon. secretaries, and duly delivered through the Parliamentary agents of the Royal Institute of British Architects to the officials of the House of Commons.

Mr. Goldsmith then read the following criticisms on the Bill by Mr. D. W. Caröe:—

We, gentlemen, are an Association engaged in the study and practice of architecture, and I would venture to invite you to give this Bill your consideration from the architect's point of view, and in this light I will name a few points.

First and foremost, we should set our faces against clauses which retain special consents to the Council, except with the greatest reservation and in cases of absolute necessity. The power of consent fosters officialism. That is quite enough to condemn its operation.

Secondly, we should oppose all clauses which will operate in exactly the opposite direction to their intention; that is to say, clauses which will conduce to the undue preservation of worn-out buildings, and militate against improvements through fear of confiscation and interference. Likewise clauses which would tend to encourage underground building, as Mr. Woodthorpe has here pointed out.

Thirdly, all clauses likely to interfere unreasonably with freedom in design, or which make, or tend to make, architecture stereotyped, should have our vigorous opposition.

Fourthly, we should remember that a Building Act should not make architecture unnecessarily costly; that the poor man's house has to be cheap as well as effective, and good for its purpose; and that no matter how costly a building be, we can (or ought) never to afford to spend money upon silly fads, or fictions, or prejudices, even for the imaginary benefits of insurance companies.

Mr. Roberts, of the County Council, in this room told us that the new Bill had for its object "the revival of building of a higher standard than had been maintained in the past."

Now the County Council's idea of such a perfect London constructed up to a high standard of building (or architecture, I suppose Mr. Roberts meant) seems to be a London of two storeys and one in the roof—so far as the Council can make it so.

If you will take an ordnance map and set up new buildings limited as proposed upon the sites in any quarter where London is rich and busy, you will see how just this estimate is of the application of Part IV. to new buildings on old sites. Can it be that the County Council has learnt to love the beautifully ornamented productions of the jerry-builders in the suburbs, erected in the genuine vernacular of their craft, and wishes to see all London cast to the same model?

You may, perhaps, be surprised to learn that the "shaving clause," so well called by Mr. Tavenor Perry—I think invented originally by the Local Government Board—has been, in a modified form, in operation in the city of Liverpool since 1890. But Liverpool has guarded itself to some extent. The rule applies there only to dwelling-houses, so that buildings devoted to office and such like purposes are exempt from its operation, while proper sanitary provision is made for residential caretakers. Now this is very different to the proposal of the County Council, but it must be borne in mind that what operates well in Liverpool or other provincial towns in such a matter will not necessarily apply to London, which is mixed, as to the character of its buildings in juxtaposition, as probably no other city in England is. Bearing in mind, also, that a tall building may make an otherwise perfectly sanitary small one too close to it quite unfit for habitation, it is not certain that the Liverpool by-law is the best, from its framers' own point of view. It is interesting to know that already there is a proposal in Liverpool head official quarters to modify the rule, by allowing buildings consisting of shops or offices on the ground floor and dwelling-houses over to be more leniently dealt with. It is suggested to allow the shops to cover the whole site, with a flat and skylight at back, and the limiting angle to be measured from the back of the flat at the first floor level. In urging some such recommendation for the Metropolis I would, however, press for a small but reasonable area, perhaps proportionate to the site, being insisted upon to light and ventilate the basement. Now I am happy to be able to state to you that the County Council have followed to some extent the lead of Liverpool. In the printed amendments to the Bill the shaving clause in all its rigour is to apply only to new domestic buildings in new streets. New clauses are introduced to apply to new domestic buildings in old streets. Briefly stated, these determine the height by making it twice the base, or, in other words, the angle is to be 63° 20' instead of 45° measured as before. Dwelling-houses having an area of less than six squares, and dwelling-houses to be occupied by more than two families, which are not on the public way, are dealt with by special provisions, and the height of warehouses is regulated when in close proximity to such dwelling-houses. Old buildings are not to offend against the provisions regulating new buildings in old streets more than they do at present. So far, let us be thankful; but in considering even these amendments there are two aspects of the question which must not be overlooked. By lack of sufficient space and air within it, as well as by lack of space without and around it, a building may become insanitary, and this especially applies to those buildings which are not, but ought to be, specifically defined in the Bill, and specially provided for, viz. buildings erected and used chiefly for purposes of trade or commerce, and which, therefore, are occupied during the day by a large number of *employés*. If the air around such a building be somewhat confined, it will still be fresher than the air inside an overcrowded building surrounded by the freshest air.

I mention this point specially in connection with the proposal to allow shops to cover most of the site as one deserving much consideration, as an antidote to any too drastic laws, framed for the admitted importance of getting rid and preventing the erection of rookeries, but applicable unduly to buildings of quite a different character.

The decrease of habitable space proposed under the operation of the Bill—even as amended—means, necessarily, the increase of the borders of the City. One may well ask where the fresh breezes are to blow from which are to keep the centre of the City in health, if still greater spur than exists already be given to its spreading out into the surrounding country.

Finally, in this connection I would protest on the score of sound construction, of dignity in architecture, and of breadth of design in our new streets, which (when the County Council has swallowed the lollipop of betterment) we hope may be many, against any rule which has any angular measurement for its chief factor, and which would cut our new buildings into fragments of all heights and shapes, and tend to create a city of wedges, the thin end always uppermost striving to insert itself into the disabilities forced upon us by Part IV. of the Act.

With regard to general architectural considerations, a clause is required which will allow houses with their offices, stables, lodges, &c., in the suburbs to rank as one. Although each of these may happen now to be removed 30 feet or 60 feet from adjoining property, as the case may be, they may be within the specified distance of one another, and thus the disabling provisions of the Building Act come into force where never intended.

In all cases, provided an adequate architrave of incom-

bustible material is used, with a definite projection say of 3 inches, timbers in window openings should be permitted out to the wall face. The present Building Act was regulated to suit the exigencies of the stucco Victorian era of Classical or Renaissance architecture, in which the detestable window reveal was desired. To secure it, perhaps, a sham fire scare was created, or may be its originator held a brief from the insurance companies, and got them, like Mr. Hall, to threaten increased premiums to further his wicked architectural ends.

I might tell you that Mr. Hall introduced me to one of his insurance companions, to whose blandishments he expected me, no doubt, to fall as ready a prey as he himself had done. I bowled that gentleman out, however, in the space of something less than a minute, found that he was not fully aware what a party-wall parapet was, had never considered its existence, and he also informed me that "fires did spread sometimes through defective party walls." That I could have taught him, and for that reason and others I have advocated the admirable Liverpool system of separate side walls.

Serious injury will be done to design if a Mansard roof cannot have a steeper angle than the 75 deg. proposed; 83 deg. at least should be possible. Grave interference will accrue to certain forms of plans necessary, on confined sites, by the operation of the sub-section dealing with light and air in the wells of houses. The clause relating to the enclosure of lifts, which is amended so as to permit of lifts in wells of staircases, requires still further amendment.

One would like to see clauses introduced for the encouragement both of reasonable projections and gables in street fronts. Moreover, under given conditions, the clause that one wall may not overhang another should be inoperative if the construction can be carried out to the satisfaction of the district surveyor. The advantage and importance in design of having limited freedom, even to a few inches, will come home to all of you. The limitations as to cornices should be amended. The projection should be measured from the wall face, and should be allowed to vary with the width of street, so as to thus allow setting back if a great projection is required by the designer.

After the reading of the papers, remarks were made by Messrs. Collard, Brodie, Beale and Banister Fletcher.

A vote of thanks having been passed to Mr. Goldsmith, the meeting, which was practically held before empty benches, terminated.

TECHNICAL MUSEUMS AND SANITATION.*

I PROPOSE with your permission to deal rather briefly with my subject this afternoon, for two reasons: first, the notice I had from your excellent secretary was somewhat short, and, since I received his intimation, my time has been unfortunately very fully occupied with business matters. My notes are therefore necessarily of a limited character, in fact, they were non-existent forty-eight hours ago, for which I feel that I owe you an apology. There is, however, another reason why my paper should be short, viz. that I propose to throw out a few suggestions in the hope that they may be productive of discussion, as I consider that an interchange of views on a matter which has not yet met with much public attention will be of value.

The subject I have been asked to consider with you this afternoon is, "The Advantages of Technical Museums in Advancing Sanitation." The word "sanitation" has a wide meaning, but I will refer to it in its more restricted sense. I may, perhaps, define it, for our present purpose, in the following manner. Firstly, domestic hygiene, including food, clothing, warming, lighting, ventilation, cleanliness and the proper use of water and drainage fittings; with this branch of sanitation every good housewife (whatever her station in life) should be acquainted.

Secondly, engineering as applied to local hygiene, embracing all matters relating to house-drainage, internal water-supply and the structural conditions which govern the healthy occupation of the dwelling.

During the past few years much has been spoken and written on technical education, and since the passing of that useful measure, the Technical Instruction Act, in 1889, technical classes and workshops have sprung into existence in almost all parts of this country. Few measures of a broader or a more practical character have found their way into the Statute book, which a glance at the official list of subjects under the conditions of Section 8 of the Act will show. In looking over this list some three years ago, I found that the following, amongst many other branches of science and art, were included, viz. domestic hygiene, plumbing, plasterers' work and sanitary engineering, carpentry and joinery, mechanical and architectural drawing, &c.

It then occurred to me that the intention of the Act could best be advanced by enabling students to obtain useful object-lessons in some at least of the subjects I have named.

With this in view I obtained permission from the Hornsey Local Board to erect a small iron building, on a site belonging to the Board, at Highgate, for the reception of such exhibits as manufacturers and others might be found willing to send, and in this novel movement I had the cordial support and the benefit of the experience of a gentleman who has devoted his energies for nearly fifty years in furthering the education and general well-being of London's working men—I allude to Mr. H. R. Williams, J.P., the chairman of the Hornsey Local Board and of the works committee of the Middlesex County Council. From this modest beginning has resulted what is, I think justly, termed a unique collection of sanitary appliances, working models, &c.

The success which has attended this museum since its opening fourteen months ago has been due to the liberal and enterprising spirit with which the principal manufacturers of this country met the invitation to exhibit, and have given to the public without charge specimens of some of the best and most novel sanitary appliances which modern science and skill could produce, and I take this opportunity of again publicly tendering to them my best thanks for their generous co-operation.

To enable you to judge of the present extent of the Highgate Museum and the advantages which it affords to technical education in North London, I will just mention the following facts. The present buildings have a floor-space of upwards of 5,300 feet super, and comprise a large lecture and drawing-room, plumbers' workshops with bench accommodation for forty-one students and five rooms containing upwards of 1,400 exhibits. These include almost every kind of sanitary appliance, both ancient and modern. Many of the exhibits are fixed and water is laid on, so that the student or other visitor can examine the fittings in actual work. Machines are provided for testing bricks, stone, cement, drain-pipes, water-fittings, &c., and students are instructed in the working of the testing apparatus and are enabled to see and appreciate the practical value of such tests to both the manufacturer and the user. The principles of ventilation and heating and the passage of air-currents through pipes are practically demonstrated. Some of the exhibits are shown in section, so that a knowledge of their form and construction can be easily obtained. In illustration of this I have placed a few water-taps, &c., on the table to show how the interior of the fittings are exposed to view in order that their action may be made clear to the student. These taps when in the museum are placed immediately over similar fittings to which water is laid on. In the case of other fittings, such for instance as water waste-preventing cisterns, those not exhibited in section are supplemented by full-sized sectional diagrams similar to those on the walls.

I think it will be readily admitted that knowledge derived in this way must have far more practical and lasting effect than that gathered from books, however well written or illustrated. The object-lessons taught by such a collection are not only more easily learned by the observant student, but the mind aided by the sense of sight and touch can better retain the information thus acquired. Lecturers and other instructors, including the professional crammer, have repeatedly testified to the advantages which students have derived from visits to the museum. In allusion to cramming, I may observe in passing that this system of helping young men to dodge the examiners, and scrape through their examinations with mere superficial knowledge, is every year becoming more common. I have acted as examiner for several years, and therefore can testify to the extent that cramming is now practised. If it were not divulging secrets, I could tell you some amusing anecdotes as to the slips sometimes made by these "stuffed students" when undergoing examination. Bad as the system is of superficially storing the memory with knowledge likely to serve some particular occasion only, and which in the ordinary course of things is soon forgotten, yet by the aid of object-lessons given in technical museums the crammed one may hope to retain permanently some, at least, of what the coach has thrust upon him.

During the educational term there are three classes held weekly at the Highgate Museum, under the direction and at the cost of the Middlesex County Council, and we have the co-operation of the Worshipful Company of Plumbers in connection with the instruction given in plumbing. These classes are well attended—in fact, so well that students have had to be refused admission in some cases, owing to insufficient accommodation. Practical and theoretical plumbing is taught on Wednesdays and Saturdays by Mr. George Taylor, R.P.C., and lessons are given in geometry and building construction by Mr. Walter Busbridge on Monday evenings. The instruction in both practical and theoretical plumbing is restricted to those actually engaged in the trade of a plumber, either as master, journeyman or apprentice. The classes on geometry and building construction are open to all students. In addition to these classes, evening lectures have been given to the public on domestic hygiene and sanitation by Sir Benjamin Ward Richardson and other well-known sanitarians. The museum is open free to the public on week-days, from 10.30 A.M. to

* A lecture by Mr. De Courcy Meade, delivered at the National Building Trades Exhibition.

8.30 P.M. It is under the care of a practical man, who takes a great interest in his work, and is always ready and willing to explain the use of the appliances to visitors.

The appreciation of the museum by the general public is shown by the fact that it has been visited by upwards of 18,775 persons since it was publicly opened by the Lord Mayor on December 8, 1892. Had the building been situated in a more central position, the number of visitors would no doubt have been very much larger.

Having laid before you a brief outline of what is being done in the north of London for the advancement of technical knowledge in connection with hygiene by the aid of a museum of sanitary appliances, I would ask you to consider the best method of conveying a knowledge of the elementary principles of sanitation to the masses. I feel that until this is accomplished in some measure at least, an improvement in the present low standard of sanitation amongst the working classes cannot be hoped for. We must try to bring home to the mind of the occupier of the cottage the benefits which the knowledge and practice of domestic hygiene confer upon those who obey its laws. I may be told that much has already been done in this direction, with a general reduction of the death-rate, and in proof of such an assertion the statistics issued by the Registrar-General may be quoted; but the highest medical authorities tell us that a large percentage of the present annual mortality is of artificial production and preventable, therefore we should not rest satisfied until the percentage of preventable deaths, with its attendant sickness and suffering, has been reduced to the lowest practicable point. The small diagram on the wall shows in a graphic manner how the annual percentage of mortality recedes from central London outwards; the strong black line shows the death-rate for ten years. From 1883-92 inclusive, the average was 19.8, with a zymotic death-rate of 2.91 for inner London, or "registration London," which is practically the area of the administrative county of London. Outer London had during the same decade a death-rate of 16.1, with a zymotic rate of 2.19. The average death-rate in three suburban districts—viz. Hornsey, Wimbledon and Finchley—amount to 11.5, 12.1 and 12.0 respectively, with zymotic death-rates of 1.16, 1.53 and 1.23. An explanation of the causes that influence the higher death-rate that prevails in the inner ring lie within the province of the medical officer rather than the engineer. I will, therefore, not attempt to offer an opinion thereon. I freely and gladly admit that great strides have been made towards the improvement of both the dwellings and the general surroundings of the British workman; the poor neighbourhoods have certainly undergone a noticeable change for the better during recent years, and as an illustration of the rapid march of sanitary progress, I will read an extract from Dr. Simon's second annual report to the City authorities, in which he describes the sanitary condition of the City in 1850. Referring to overcrowding, Dr. Simon said:—

"Statistics can give you no conception of this crowding. If you turn from the deceptions of an average to the exact analysis of detail, you will find many single rooms in the City with a larger number of inmates than you might otherwise ascribe to entire houses. Instances are innumerable in which a single room is occupied by a whole family—whatever may be its number, and whatever the ages and sexes of the children; where birth and death go on side by side; where the mother in travail, or the child with smallpox, or the corpse waiting interment, has no separation from the rest.

"It is no uncommon thing, in a room of 12 feet square or less, to find three or four families 'styed' together (perhaps with infectious disease among them), filling the same space night and day—men, women and children in the promiscuous intimacy of cattle."

What would the City authorities of to-day say if such a state of things were found within their borders? Yet I am not so sure that a journey a little further eastward would disclose a very marked improvement in 1894 on what Dr. Simon characterised in 1850 as "a pestilential heaping of human beings."

Much, no doubt, still remains to be done, and I would ask you not to look at the question either from an optimist's or a pessimist's point of view, but to consider it from a purely practical standpoint.

If technical museums are to have full effect in educating the general public as well as specialists, they must cover a wider field than the museum at Highgate, which is mainly devoted to sanitary engineering, and I believe this could be accomplished within reasonable limits of space and cost if elementary instruction only was aimed at. The Parkes Museum embraces a much wider area. Sir Douglas Galton, K.C.B., describes the objects that that museum was intended to illustrate in the following terms:—

1. *Engineering and Local Hygiene*, which includes climatology, and causes of disease and death-rates appertaining to physical geography, information on health-resorts, botanical hygiene, geology as bearing on salubrity and water-supply, plans for the healthy arrangement of towns, principles of town drainage, water-supply, scavenging and disposal of refuse, &c.

2. *Architecture*.—(a) Designs and models connected with health in dwellings of every sort, factories, workshops, schools, &c. (b) Materials and details of construction.

3. *Household Requisites*, including fixtures and furniture, and embracing all matters connected with lighting, warming, cooking, cleaning and other domestic sanitary purposes.

4. *Clothing*, embracing materials, shape, climatic influences, &c.

5. *Food*.—Chemistry of food and value for nutrition, as obtained either from the animal or from the vegetable kingdom. Beverages. Dietaries.

6. *Preservation and Relief*.—(a) Personal hygiene. (b) Protection and rescue, including protection against disease, poison, dangerous insects. Lifeboats. Fire-escapes. Lightning conductors, &c. (c) Industrial pathology, or the prevention of accidents, injuries, and diseases incidental to industrial employments. (d) Special hygiene of professional occupations. And Sir Douglas continues:—"You will thus see that the subjects which our Institute would illustrate are spread over the principal proceedings of our daily life. It is not that sanitary knowledge in itself is by any means new, but our progress in what we term our civilisation has developed various new contingencies attending our mode of living, which have altered the conditions which affect the application of sanitary knowledge, so that the want of an institution such as ours has come to be widely felt.

"In looking around at our mode of life in this country, at our habits, our dwellings, is there not on every side an opening for instruction in, or for comment upon, the violation of sanitary knowledge? For instance, look at the hecatombs of infants yearly sacrificed to our mismanagement.

"The Registrar-General tells us that in October, 1888, the deaths of infants in London averaged 164 per 1,000 born.

"In provincial towns the mortality was greater; thus in twenty-seven large towns it averaged 227 per 1,000 born. In Sheffield it was 279 per 1,000 born; Leeds, 294; Leicester, 359.

"Amongst the many causes which lead to this sacrifice of infant life, ignorance of the elements of hygienic treatment is the main cause, and especially in feeding, for many babies are given food that an adult could ill digest.

"When we look around at the large masses of people congregated together in London and in our large towns, we feel in despair as to what methods to pursue to induce them to regulate their lives according to the principles of health and morality.

"It would have been comparatively easy to have done so before the communities had attained their present gigantic proportions, had some far-seeing legislator recognised the importance of regulating the lives of those who dwelt together in communities; but whatever are our present difficulties, we may feel sure that they are less than those which will fall to the lot of our successors if we neglect now to grapple with them."

When dealing with any measure of reform of this kind it is, of course, necessary to carefully weigh the existing conditions, and ascertain in what direction improvement may be judiciously and permanently effected.

I have for many years (upwards of twenty) been engaged in sanitary works of various kinds; during this period it has been my duty to visit some of the most insanitary localities that existed in the Metropolis. I have therefore had special opportunities of seeing the degrading influence of dirt and squalor on the unfortunate inhabitants of these places, and also of observing the chief causes for this deplorable state of things. I have long since come to the conclusion (and subsequent experience has strengthened my views) that the present remedy does not lie in sanitary laws alone or in official vigilance. It can only be effected by the gradual education of the people, particularly the women, in the elementary rules which govern the health of all communities.

The School Boards are doing much useful work in furtherance of the object we have in view; but, as if nature had decreed that this general system of education, which is due to the advance of civilisation, should have some counteracting influence, we find that the congregating of large numbers of children together in schools is in itself an element of danger to the public health. Dr. Thorne Thorne, C.B., the chief medical officer of the Local Government Board, gives several instances in which the outbreak of disease was clearly attributable to school attendance, and, as the matter is one of wide interest and should be known and understood by all who take an interest in educational matters, I will mention the following instance quoted by Dr. Thorne Thorne with reference to outbreaks of diphtheria in schools, and the inferences he draws from the official investigations. He says:—

School influence would appear then to be operative for mischief in a number of ways.

1. It brings together those members of the community who are, by reason of age, most susceptible to diphtheria.

2. The children thus brought together are placed, and remain for many hours of the day, in exceptionally close relation with each other.

3. The closer the aggregation, and the greater the lack of ventilation, with corresponding hindrance to the free movement of air, the greater the risk.

4. Such faulty sanitary circumstances of the school-house and its surroundings, and such other conditions as tend to a condition of general ill-health, in that they induce sore throat, favour the reception by children so suffering of any imported diphtheria infection.

5. There are ample grounds for believing that the aggregation of children in elementary schools "constitutes one of the conditions under which a form of disease of particular potency for spread and for death may be, so to speak, "manufactured."

6. The practices of kissing and of transferring sweetmeats from mouth to mouth—practices which are more common amongst girls than with boys—as also the joint use of drinking-cups, &c., must, according to experience, be credited with assisting in the diffusion of diphtheria amongst school-fellows.

All this goes to show that when training youth, especially by a compulsory process, the greatest vigilance should be observed to prevent the manufacture—to use Dr. Thorne Thorne's words—"of a most fatal disease." The school building should be maintained in the best possible state of sanitation, both structurally and otherwise, and no overcrowding of any classroom, even temporarily, should be permitted. It may be thought that all this is somewhat foreign to the subject of my paper, but as I am advocating the advantages of technical museums in connection with Board and other public schools, it would be rather incongruous to recommend that children be taught sanitation in the schools, whilst the school system itself was productive of one of the very evils that a knowledge of sanitation is calculated to abate.

Can anyone suggest a better way to advance sanitation than by establishing technical museums in connection with our schools, by making elementary hygiene one of the principal subjects of the Education Code? If children (more especially the female portion of them) receive a careful training in domestic sanitation, it will only be a matter of time (not many years) until the whole standard of sanitation throughout the country is raised, with a proportionate improvement in the health, the earning powers, the comfort, and the morality of the people.

The lecture was followed by a discussion, in which the following gentlemen took part:—Messrs. Gilbert Wood, T. Freeman, H. H. Collins, Blair, Brown, and the chairman, Mr. Banister Fletcher. The usual votes of thanks were passed.

BABYLONIAN AND ASSYRIAN EXPLORATION.

ON Monday, at the Victoria Institute, Mr. Hormuzd Rassam gave a summary of the progress of Babylonian and Assyrian exploration. He remarked that fifty years ago Nineveh and Babylon were little more than names, and he went on to describe the discoveries which had been made in the last half century and the share he himself had had in them. He began work in the East in 1844, under Sir Henry Layard, and spent about ten years in exploring the sites of Nineveh, Babylon, Calah and Mosul. A long time afterwards he explored the "Tower of Babel" and the palace of the kings at Babylon, and discovered the site of Khorsabad, the city of Sargon. He lamented the changed attitude of the Turks towards explorers. From being lax they had become very strict, so much so that permissions granted by the Sultan to dig were often hedged round with so many restrictions as to be almost useless. The important thing was to be on good terms with the natives, and a little ingenuity surmounted many obstacles. Thus it was forbidden to dig among tombs, but it was a perfectly legal operation to dig a grave. In conclusion Mr. Rassam deplored the destruction wrought among antiquities by the Arabs, and urged the necessity for increased systematic exploration of the thousands of mounds as yet uninvestigated.

OFFICIAL RULES FOR SCHOOL BUILDINGS.

THE regulations of the Education Department for 1894 contain several alterations in the rules for planning and fitting-up public elementary schools, as will be seen from the following:—

School planning is the science of thoroughly adapting every part of a building, even the minutest detail, to the work of school teaching. Convenience of plan, suitable lighting, proper subdivision into classes and thorough ventilation, with warmth, but without draughts, are its leading essentials. Attention to small points is of extreme importance. Sanitary laws are here as vital as in a hospital. The school architect is recommended first to perfect his plan. His own skill should then enable him to clothe it with form, proportion, character and colour. These building rules are intended to assist school boards and their architects to produce the most compact, convenient and economical plans of school buildings. The cost of maintenance should be kept in view as much as the

capital expense. It is desirable that, before instructing an architect, the teaching staff of a school should be well considered, so that the number of rooms and the accommodation of each may be approximately settled before the expense of building is incurred.

1. Planning and Accommodation.

1. In planning a school the first thing is to seat the children in the best manner for being taught. The accommodation of each room depends not merely on its area, but also on its shape (especially in relation to the kind of desk proposed), the positions of the doors and fireplaces, and its proper lighting. The second point is to group the rooms together in a compact and convenient manner.

2 and 3. Schoolrooms.

2. Every school must have a schoolroom as hereunder, or a central hall as under Rule 8. The proper width for a schoolroom is 18 to 20 feet for long desks, or 22 feet for dual desks. If the width does not exceed 20 feet, groups of long desks, three or four in number, according to the width, must be used; if the width is 22 feet, dual desks, five rows deeps, are most suitable. (For classrooms, see Rule 7.)

a. Accommodation in schoolrooms for elder children is calculated by the number of children seated at desks and benches, subject to a minimum of 10 square feet per child being provided. (For the mode of calculating accommodation in classrooms see Rule 7, in infant schools see Rule 16 f.)

b. Double bank schools (now almost obsolete) require rooms 32 feet wide, walls left clear for three rows of desks, and ample lighting from windows on both sides extending to ceiling.

c. Wasted space cannot be considered.

3. The doors and fireplaces in schoolrooms must be so placed as to allow of the whole of one side of the schoolroom being left free for the groups of benches and desks.

a. No schoolroom lighted from one side only can be approved. The gable ends should be fully utilised for light. (See also Rules 9 and 9 b.)

4. Walls, Floors and Roofs.

4. The walls of every schoolroom and classroom, if ceiled at the level of the wall-plate, must be at least 12 feet high from the level of the floor to the ceiling; and, if the area contain more than 360 superficial square feet, 13 feet, and, if more than 600, then 14 feet.

a. The walls of every schoolroom and classroom, if ceiled to the rafters and collar-beam, must be at least 11 feet high from the floor to the wall-plate, and at least 14 feet to the ceiling across the collar-beam.

b. Great care should be taken to render the roofs impervious to cold and heat.

c. Roofs open to the apex are not approved. They can only be permitted where the roofs are specially impervious to heat and cold, and where apex ventilation is provided. Iron tie-rods are least unsightly when placed horizontally.

d. The whole of the external walls of the school and residence must be solid. If of brick, the thickness must be at least one brick and a half, and if of stone, at least 20 inches.

e. All walls, not excepting fence walls, must have a damp-proof course just above the ground line.

f. The whole area of the building should have concrete 6 inches thick under the ground floor, and air bricks for ventilation to joints.

g. Timber should be protected from mortar and cement by asphalt or tar.

5. Entrances.

5. Entrances should be separate for each department. In large schools more than one entrance to each department is desirable. The principal entrances should never be through the cloak-room. Entrance doors should open outwards. A porch should be external to the schoolroom.

6. Cloak-rooms.

6. Cloak-rooms must be external to schoolrooms and classrooms with gangways at least 4 feet wide, amply lighted from the end. Hat-pegs should be 12 inches apart, numbered, and of two tiers. The hanging space necessary to provide a separate peg for each is thus 6 inches lineal per child.

7. Classrooms.

7. Classrooms are calculated at 10 square feet if not providing accommodation for more than sixty children. Six rows of dual desks or four rows of long-length desks are permissible in such classrooms. When the front of a class is narrowed, but the area of the room is not reduced, a seventh row of dual desks or a fifth row of long desks may be allowed. Rule 2 applies to all rooms providing accommodation for more than sixty, or being more than 24 feet 8 inches deep from the window wall.

a. The minimum size of classroom is 18 feet by 15 feet. If desks are placed longitudinally the width should not be less than 16 feet. This latter width is also allowed in schoolrooms of very small size.

b. The classrooms should never be passage-rooms from one part of a building to another, nor from the schoolrooms to the playground or yard, and should be on the same level as the schoolroom. Each should be easily cleared without disturbance to any other room.

c. The number of classrooms should, where practicable, equal the number of classes in the schoolroom.

d. The excessive use of movable partitions should be avoided.

8. Halls.

8. Large schools are sometimes planned with a central hall, from which the classrooms are entered, and which is not, as a rule, calculated in the accommodation.

But in the case of mixed schools an exception is made, one class being necessary in the hall in order to secure a teacher's supervision of the separate exits to the latrines (see Rule 13 *a*). The hall must, therefore, be suitable for teaching such class; it must be fully lighted, warmed and ventilated, and must contain a floor space of not less than 1,200 square feet, and the position of the class should be marked on the plan.

9. Windows.

9. Every part and corner of a school should be fully lighted. The light should, as far as possible, and especially in classrooms, be admitted from the left side of the scholars. (This rule will be found greatly to influence the planning.) All other windows in classrooms should be regarded as supplementary, or for summer ventilation. In cases where left light is impossible, right light is next best. Windows full in the eyes of teachers or scholars are not approved. In rooms 14 feet high any space beyond 24 feet from the window wall is insufficiently lighted.

a. Windows should never be provided for the sake merely of external effect. All kinds of glazing which diminish the light, and are troublesome to keep clean and in repair, should be avoided. A large portion of each window should be made to open for ventilation and for cleaning.

b. The sills of the main lighting windows should be placed about 4 feet above the floor, and the tops of some should always reach nearly to the ceiling. The ordinary rules respecting hospitals should here be remembered. Large spaces between the window-heads and the ceiling are productive of foul rooms.

c. Skylights are objectionable, and should never be resorted to where windows are possible. Plans needlessly involving their use cannot be approved, except in the case of central halls having ridge or apex ventilation.

10. Staircases.

10. A staircase like a porch must be external to the schoolroom. No triangular steps or "winders" should be used. Each step should be about 13 inches broad and not more than 6 inches high. The flights should be short and the landings unbroken by steps. The number of staircases should be sufficient not only for daily use, but for rapid exit in case of fire or panic.

11. Ventilation.

11. Apart from open windows and doors, there should be provision for copious inlet of fresh air; also for outlet of foul air at the highest point of the room; the best way of providing the latter is to build to each room a separate air chimney carried up in the same stack with smoke flues. An outlet should have motive power by heat or exhaust, or it will frequently act as a cold inlet. The principal point in all ventilation is to prevent stagnant air. Particular expedients are only subsidiary to this main direction. About $1\frac{1}{2}$ superficial inches per child for outlets and rather more for inlets is desirable.

a. Although lighting from the left hand is considered so important, ventilation in summer demands also the provision of a small swing window as far from the lighting as possible, and near the ceiling.

12. Warming.

12. The warming should be moderate and evenly distributed so as to maintain a temperature of from 56 degs. to 60 degs. When a corridor or lobby is warmed the rooms are more easily dealt with, and are less liable to cold draughts. Where schools are wholly warmed by hot water the principle of direct radiation is recommended. In such cases open grates in addition are useful for extra warming occasionally, and their flues for ventilation always.

a. A common stove, with a pipe through the wall or roof, can under no circumstances be allowed. Stoves are only approved when (i.) provided with proper chimneys, as in the case of open fires; (ii.) of such a pattern that they cannot become red hot, or otherwise contaminate the air; (iii.) supplied with fresh air, direct from the outside, by a flue of not less than 72 inches superficial; and (iv.) not of such a size or shape as to interfere with the floor space necessary for teaching purposes.

b. A thermometer should always be kept hung up in a school.

13. Sanitary Arrangements.

13. Water-closets within the main school building are not desirable, and are only sanctioned for women teachers. All others should be at a short distance, and completely disconnected from the school.

a. The doors, staircases and passages leading from the schoolroom to the latrines (whether in mixed or in other schools), and the latrines themselves, must be separate for the two sexes, and constructed entirely apart from each other. In the case of a mixed school this rule especially affects the planning. Where passages or corridors are unavoidably used by both sexes, there must be complete supervision from the classrooms by sheets of clear glass.

b. Each closet must be separate, fully lighted and ventilated, and properly screened or supplied with a door. More than one seat is not allowed in any closet.

c. The children must not be obliged to pass in front of the teacher's residence in order to reach their latrines.

d. The following table shows approximately the number of closets needed:—

		For Girls.	For Boys.	For Infants.
Under 30 children	.	2	1	2
" 50 "	"	3	2	3
" 70 "	"	4	2	3
" 100 "	"	5	3	4
" 150 "	"	6	3	5
" 200 "	"	7	4	6
" 300 "	"	8	5	7
		Urinals in proportion.		

e. Cesspools and privies should only be used where unavoidable, and should be at a distance of at least 20 feet from the school. Earth or ash closets of an approved type may be employed in rural districts, but drains for the disposal of slop and surface water are still necessary. The proximity of drinking-wells should be carefully avoided.

f. Soil-drains must always be laid outside the building (on a hard even bottom of concrete) in straight lines, with glazed stoneware pipes, carefully jointed in cement, and made absolutely water-tight. A diameter of 4 inches is sufficient unless for drains receiving the discharge of more than 10 closets. Above this number the diameter should be 6 inches. The fall should never be less than 1 in 30 for 4-inch, and 1 in 40 for 6-inch drains. An inspection opening or chamber should be provided at each change of direction, so as to facilitate cleansing the drain without opening the ground. Every soil-drain must be disconnected from the main sewer by a properly constructed trap placed on the line of drain between the latrines and the public sewer. This trap must be thoroughly ventilated by at least two untrapped openings, one being the 4-inch soil pipe carried up full size above the roof, and the other an inlet pipe connected with the side of the trap furthest from the public sewer. Automatic flushing tanks are desirable where trough closets are used.

g. Urinals must in all cases have a sufficient supply of water for flushing.

h. Waste pipes from sinks or lavatories should be first trapped inside and then made to discharge direct through the wall over a trapped gulley.

14. Desks.

14. Benches and desks, graduated according to the ages of the children, should be provided for all the scholars, and placed at right angles to the light. (See also Rules 3 *a* and 9.)

An allowance of 18 inches per scholar at each desk and bench will suffice (except in the case of the dual desk), and the length of each group should therefore be some multiple of 18 inches, with gangways of 18 inches between the groups and at the walls. In the case of the dual desk the usual length is 3 feet 4 inches, and the gangways 1 foot 4 inches.

a. The desk should be very slightly inclined. An angle of 15 degs. is sufficient. The objections to the inclined desk are that pencils, pens, &c., are constantly slipping from it, and that it cannot be conveniently used as a table. The objection to the flat desk is that it has a tendency to make the children stoop. A raised ledge in front of a desk interferes with the arm in writing.

b. As a general rule, no benches and desks should be more than 12 feet long. And no group of long desks, in a schoolroom providing for more than 60 children, should contain more than four rows of benches and desks (or three, if the width is less than 20 feet), because in proportion as the depth is increased the teacher must raise his voice to a higher pitch; and this becomes exhausting to himself, while at the same time it adds inconveniently to the general noise. With the use of the dual desk the space between seat and desk disappears, as the children stand in the gangways.

15. *Sites and Playgrounds.*

15. Every school should have an open airy playground proportioned to the size and needs of the school. The minimum size of site is, in the absence of exceptional circumstances, a quarter of an acre for every 250 children. If the school is of more than one storey this area may be proportionally reduced. The minimum open space is 30 square feet per child.

a. In the case of a mixed school, playgrounds must be separate for the boys and girls.

b. All playgrounds should be properly levelled, drained, enclosed and fitted with some simple appliances. A portion should be covered, having one side against a wall. A covered way should never connect the offices with the main building. Buttresses and corners should be avoided.

c. An infant school should have its playground on the same level as the school.

16. *Infant Schools.*

16. Infants should not, except in very small schools, be taught in the same room with older children, as the noise and the training of the infants disturb and injuriously affect the discipline and instruction of the other children.

a. There must be no opening wider than an ordinary doorway between an infants' and any other schoolroom, because of the sound of the infant teaching.

b. An infant school and playground should always be on the ground floor, and if more than 80 scholars are admitted, should have one gallery and a small group of benches and desks for the occasional use of the elder infants.

c. No infant gallery should hold more than 80 or 90 infants. It should be well lighted from one side. The light for object lessons is as good from the right as from the left.

d. The width of an infant schoolroom should be in proportion to its size, but not more than 24 feet. A covered marching-ground is desirable.

e. The babies' room should always have an open fire, or be maintained at a temperature of about 65 degrees.

f. The accommodation of an infant school is calculated at 8 square feet for each child, after deducting wasted or useless space, but a larger area should be allowed wherever practicable. Care should be taken that the numbers are conveniently seated and that space is left for marching. Where a second standard is taught in an infant school the accommodation for it is calculated at 10 square feet per child.

17. *Cookery Centres and Classrooms.*

17. A cookery centre should be capable of accommodating at least one class of twenty-four at practice and not more than seventy-two at demonstration at one time. A cookery classroom should contain at least 400 superficial feet, and be approached by a separate entrance in the girls' playground. A small scullery is necessary, and a bonnet-room.

18. *Workshops and Laundries.*

18. Workshops and laundries are best entirely apart from the school.

19. *Teacher's House, &c.*

19. The residence for the master or mistress should contain a parlour, a kitchen, a scullery and three bedrooms, and the smallest dimensions which their lordships can approve are—

a. The residence must be so planned that the staircase is immediately accessible from an entrance-lobby and from the parlour, kitchen and each bedroom, without making a passage of any room.

For the parlour	12 ft. by 12 ft.	} of super- ficial area ;	{ 8 ft. } in height to wall-plate. 8 ft. } if sealed at wall-plate, or 7 ft. to wall-plate and 9 ft. to ceiling.
" kitchen	12 ft. by 10 ft.		
" one of the bedrooms	12 ft. by 10 ft.		
" two other bedrooms	9 ft. by 8 ft.		

b. Each bedroom must be on the upper storey, and must have a fireplace.

c. The parlour must not open directly into the kitchen or scullery.

d. There must be no internal communication between the residence and the school.

(e) Windows should be carried up as nearly to the ceilings as practicable.

(f) There must be a separate and distinct yard, with offices.

(g) A caretaker's house need not be quite so large.

(h) All houses should be separate from, and not built as part of, the schoolhouse.

20 and 21. *Loans.*

20. No loan of money can be obtained from the Public Works Loan Commissioners unless the whole cost of the school, exclusive of site, legal expenses, extra rooms for instruction authorised by the Code and residences (if any) is kept within the sum of 10*l.* per child accommodated. An allowance will also be made in reference to the cost of a central hall not calculated in the accommodation (Rule 8). Rooms for extra subjects recognised by the new Code, such as drawing, chemistry, &c., will have an allowance varying from 15*s.* to 20*s.* per square foot.

From 275*l.* to 400*l.* will be allowed for a caretaker's house. From 275*l.* to 500*l.* will be allowed for a cookery centre. Whether the necessary loan be borrowed in the open market or not, extravagant plans cannot be approved.

21. The Department do not entertain applications for loans when the expenditure has been incurred without their previous sanction.

THE BIRMINGHAM SCHOOL OF ART.

IT is well known that the Birmingham Corporation, while accepting the South Kensington administration as a sort of burthen which has to be sustained, take care that the elasticity of their school cannot be overcome. The museum and art gallery committee have no objection to admit that, when tested by the machinery for examination which is employed by the Department, the Birmingham school stands conspicuously at the head of the schools of art in the United Kingdom, for that result has been attained by a training which is not inspired from South Kensington. What the Corporation and the people of Birmingham accept as a test of the progress of the school is the report which is prepared by one of the local artists, who can realise how far the school can aid in the advancement of local industries. This year Mr. W. J. Wainwright was appointed examiner, and he has sent in the following report on the works he saw in February last :—

"It will be seen from the detailed report on each competition that the year's work has been productive of satisfactory results. It has been a good steady year ; very little falling off, and what falling off there is, is more than sufficiently compensated for by the progress made to insure a balance on the right side. The greatest advance of the year has been made in elementary design at the Central, and in design in all sections at the branch schools, both drawn and modelled. At the Central School this advance, it would appear, is immediately due to the influence of the lectures by Messrs. Jackson and Morgan. The work resulting from those lectures is far better and more extensive than any that had previously been done in that way. At several of the branch schools an exhilarating briskness and enterprising spirit of emulation characterise all the work. The applied design is taking an increasingly important position in the school, as will be evident when the works are publicly exhibited. There is one undesirable class of work in the design sections the existence of which is due to circumstances external to the school—*i.e.* the laborious, careful outline designs, done for the purpose of obtaining certificates, and the chief aim of which appears to be a characterless perfection. This work is evidently a penance to those who do it. It can never commend itself to the designer ; it is ignored by the manufacturer, because it has no practical value ; to the examiner it is an enigma, to the student a delusion. These drawings are in this school a lingering remnant of what was once its dominating spirit. I have commented thus upon the only undesirable work with which I have had to deal, firstly, because it is so well done ; and, secondly, the school having outgrown it long ago, it is fitting that a final statement concerning it should appear in this annual report, were it for no other purpose than to discriminate it as a misapplied study in design towards which responsibility rests not with the school directorate. In industrial art training there is little room for the abstract. All endeavour should from the beginning be directed towards an application. This has now for many years been the aim and purpose of the teaching of this school ; and although the results of that teaching have been subjected to the onslaught of that perennial critic the "practical man," it is only those who know from internal knowledge the difficulties which have stood in the way who are aware how unreasonably exacting that critic has often been. The difficulty to which I now allude is the difficulty of having to teach the student to do a thing without having the means of demonstrating to him practically how it should be done. The old adage which differentiates between theory and practice has no truer or more forcible application than in industrial art training. If students are to be taught industrial design so as to be of the greatest use to themselves and to the community, they must have access to, and practice in, the art workshop. They must acquaint themselves with the nature of the materials of which they propose to treat, and with the processes and the possibilities of the processes by which those materials can be treated. Thus informed, the creative artistic mind is prepared to originate effects which the most prolonged and careful theoretical teaching could never bring about. The office-trained designer is a creation of this century, and it is to be fervently hoped that this century will close over the system which has stamped the industrial art of this country with its worst characteristic, causing whole lives to be spent, not in endeavouring to give expression to artistic idea by a proper treatment of material, but in the torturing of material to the realisation of fascinating impracticabilities in pencil and colour, by which the adroit designer too often captivates the untutored fancy of a confiding public. Nor will this state of things be remedied until the designer is master of the

material for which he designs, and the workman elevated by art training from the level to which he has been reduced. It is not until this position is understood that the student, and for that matter the community at large, can realise the influence upon the art of the country which the setting up of the art laboratory portends. It is premature thus early to look for results from the very important and necessary additions in the art laboratories, but what those results will include is indicated by the effect which the now-established *repoussé* work has had on the character of designs made by students who have already executed designs in metal. One sees at once that it has been the aim of the student to express on paper only what the mind has already foreseen in the metal, discarding all attempt to invest the drawing with any quality having no bearing on the work to be produced. In other words, there is each year a larger proportion of the design work possessing all the requirements of the practical design ready to the hand of the producer. After careful examination of the year's work in the school, and finding so much advance has been made in directions already particularised, I am of opinion that the capacity of the teaching staff has never been so brilliantly evident as at the present time. Nor has the work of the school ever contained the same proportion of efforts informed with fine feeling for the higher styles, and instinct with an inner sense of quality, so difficult to express, so essential for the life of art; and what is perhaps most significant is that these qualities are not confined to experienced students who are pursuing the higher studies, but are evident in the works of students who are little more than beginners, thus showing that, from the earliest steps in design, the progress of the student is assured, so far as it can be assured, by right direction."

Mr. Wainwright's remarks should be carefully considered by every committee associated with an art school in Great Britain. The "exhilarating briskness and enterprising spirit of emulation" of which he speaks are qualities which are unknown in most of the departmental schools. For long years Birmingham, like other towns, was compelled to plod wearily in the track which the clerks at South Kensington prescribed. Mr. Wainwright prays that the system of "torturing of material to the realisation of fascinating impracticabilities in pencil and colour" may come to an end with the century, but as long as able Academicians and other artists are to be found to pose as industrial experts, how is the reform to be attained? If half a dozen manufacturers were allowed every year to examine the works of the schools, we might then believe the beginning of the end for fascinating impracticabilities was drawing nigh.

The Oxford Museum.

SIR,—The reprint of the book on the Oxford Museum brings vividly to mind a most interesting chapter in the history of art and science. Forty years ago the erection was watched with high hopes as a new departure in the art of building, and as the realisation of theories which Mr. Ruskin had urged with such incomparable eloquence. Two letters from him to Sir Henry Acland are eminently characteristic in their summing-up of his whole creed.

The Museum was built in 1859, to give to the study of natural history and medicine the same advantages as the schools of classics, history and theology. The study of science had no encouragement at Oxford, and when the proposal was made to build the Museum the fiercest opposition was aroused, partly owing to the opinion of one Vice-Chancellor, that science tended to infidelity; but it is particularly interesting to read that Dr. Pusey openly advocated scientific study, and that if it had not been for him and his friends the final vote for the Museum would have been lost. Thirty thousand pounds were grudgingly voted, and the question had to be determined what style of architecture would best combine beauty and convenience. This was Mr. Ruskin's opportunity, and, after a sharp contest, he won the day. Architects were invited to send in designs, and in due course the first prize (Gothic) was awarded to Sir Thomas Deane and Mr. Woodward, of Dublin; and the second, 200*l.* (Renaissance), was divided, as of equal merit, between Mr. Barry, of London, and Mr. Travis (Travis & Mangnall), of Manchester. It was a moment of supreme importance to Mr. Ruskin and to the enthusiastic group of artists who felt that it was a turning-point in the history of art. The very difficulties and limitations which beset the undertaking were an additional interest to Mr. Ruskin, who could thus see put to the severest test his conviction that "the essence and power of Gothic lies in its adaptability to all needs."

Another interesting feature in the history of the building is that its details were entrusted to Irish workmen brought over by the architects, who had had experience of them in building the Trinity College Museum in Dublin, and their work was

a source of high satisfaction to Mr. Ruskin—it was the "first building in the country the ornamentation of which was entrusted to the invention of the workmen." Thus the capitals were all original studies of flowers and animals instead of being servile copies of old examples.

The Queen presented five statues, and Mr. Gladstone, Dr. Pusey and the Duke of Argyll were amongst the many contributors.

It is satisfactory to find the author of the vigorous address of 1859 still unswerving from his beliefs, and confident in the work which nearly half a century ago he helped to initiate.—
Your obedient Servant,
HERMES.

GENERAL.

An Iona Cross, designed by Mr. Pearson, R.A., is proposed for erection on the highest crest of the Down at Freshwater, as a memorial of the late Poet Laureate.

Mr. G. D. Oliver, of Carlisle, has gained the first prize in the competition for the new infirmary at Whitehaven.

A Statue of the late Rev. Dr. Hanna was unveiled in Belfast on Saturday. It is the last work of the late G. B. Birch, R.A.

Mr. R. Hammond, consulting engineer to the Coventry Corporation in respect to electric lighting, has been awarded by the Morley Corporation, in an open competition, the premium of 100 guineas for the best electric-lighting plan for the borough.

Messrs. W. & G. Shearburn have been successful in the competition for the Oddfellows' Hall, Dorking.

A Grammar School is to be erected in Paisley in accordance with the terms expressed by the W. B. Barbour trustees, who have presented to the School Board the sum of 15,000*l.* for that purpose. Mr. D. Barclay will be the architect.

At All Saints, Plymouth, four large single lights in the apse are now fitted with painted glass. They represent patron saints of some of the guilds of the parish. The figures are very large, standing upon simple bases and under canopies, with quarry work at top and bottom. They are the gift of the vicar, the Rev. C. R. Chase, and have been carried out under the direction of Mr. Edmund Sedding, architect, of Plymouth.

A Reredos was unveiled on Easter Day at Holy Trinity Church, Micklegate, York. It is of pine, carved in the Perpendicular style. The carving was executed by Milburn, of York, from designs of Mr. Hodgson Fowler, of Durham.

A Stained-glass Window over 30 feet in height will be among the contributions to this year's Salon. It is the work of M. Champigneulle and was designed by M. Albert Maignan. The subject is one of the combats of Joan of Arc.

The Statue of an Angel about 22 feet in height has been placed on the upper platform of the Tower of St. Jacques, Paris, which is about 176 feet from the street level.

The Prince Regent of Bavaria has conferred the order of St. Michael on the following French painters:—MM. Jean Paul Laurens, Cormon, St. Marceaux Doucet and Maignan.

An Exhibition of statuary models, paintings and sketches by Carpeaux, the sculptor of the *Dance* group before the Opera House, will shortly be held in the Ecole des Beaux-Arts, Paris.

Mr. Lewis E. Isaacs will read a paper on "The Construction of Roads and Streets from a Sanitary Point of View" at the meeting of the Sanitary Institute on Wednesday, the 11th inst.

M. George Bechmann, chief engineer of bridges and roads, and chief of the sanitary works of Paris, will read a paper on "Sanitation in Paris" at the meeting of the Sanitary Inspectors' Association at Carpenters' Hall to-morrow (Saturday).

Mr. R. Lane, Q.C., the magistrate at the North London Police-court, has decided that a photographer's show-case is not a building as defined in any of the Metropolitan Building Acts, and has awarded costs against the London County Council, by whom the owner was summoned for setting it up without obtaining consent.

Mr. H. T. Hinks has purchased the property known as "The Friary," Lichfield, which was formerly a monastery, and abounds in historic associations. It was founded early in the thirteenth century by Bishop Stavenby, Bishop of Coventry and Lichfield, but seventy years later it was destroyed in the great fire which demolished almost the whole of the city. The present house was built in 1545.

An Exhibition of oil-paintings and monochromes (sea and land scenes, fruit and flowers), by Mr. Hamilton Marr and Mrs. Sophie Marr, will be soon held at the Gallery, 9 Conduit Street, Regent Street.

The Technical Commission on the Nile propose to raise the temples at Philæ to a higher level in order that they may be preserved without preventing the construction of the dam at Assouan.

The Architect.

THE WEEK.

At the meeting of the Institute of Architects on Monday evening, Mr. THOMAS BLASHILL read a paper on the London County Council Chamber, Spring Gardens, and described the work of enlargement and reconstruction, which had been carried out under his supervision. Erected in 1861 from the designs of the late Mr. MARRABLE, the building was rectangular, 55 feet by 30 feet and 30 feet high. For purposes of enlarging the only space available was on the north side, and this space he utilised for the construction of an addition with apsidal or semicircular termination, but it had involved changing the axes of the building. In the reconstruction Mr. BLASHILL had adhered to the lines of decoration and internal treatment adopted by Mr. MARRABLE in his designs. Mr. BLASHILL described in detail the work of reconstruction, the chief point of interest being perhaps that the acoustic properties of the chamber were better than ever—the height of the enlarged chamber not having been altered, but kept at 30 feet as before. The room underneath the apsidal addition to the chamber was utilised for the architect's department, accommodating from twenty to thirty clerks. Of course it was only natural for Mr. BLASHILL to say that if he had to design a council chamber with a free hand he would have considerably altered the plan. In the discussion that ensued, Mr. BRYDON, who seconded a vote of thanks to Mr. BLASHILL, proposed by Mr. ASTON WEBB, spoke of council chambers for provincial Councils, and laid great stress on perfect noiselessness, which Mr. BLASHILL had explained was the case at Spring Gardens. Mr. WILLIAM WHITE, Mr. C. FOWLER, Mr. WILLIAM WOODWARD, Mr. JOHN HUTTON, and Professor KERR also joined in the discussion.

In the Glasgow Sheriff Court judgment has been given in a case where the plaintiff claimed 500*l.* as compensation for the illness and deaths of members of his family, caused by the defective condition of a house in Langside belonging to the defendants. The annual rent was 45*l.* On taking the house the plaintiff was assured that the drains were in good order, for they had sustained the smoke test. Afterwards, when illness attacked his family, the plaintiff applied to the local sanitary inspector, and it was found that the drains were in an unsatisfactory state. It was proved that successive attacks of diphtheria were to be ascribed either directly to the drains, or indirectly by lowering the victims' system until they became susceptible to attacks. The defendants maintained that the plaintiff should have left the house, when he discovered its dangerous condition. The Sheriff said there was no absolute rule on this subject, and a man was not bound to leave a house simply because he thought there was something wrong with the drains. It was a serious thing to leave a house and find yourself in collision with your landlord. If a man were satisfied that the drains were wrong and the landlord said he would do nothing, then he ought not to expose himself to a peril which the landlord said he would not remove. But where a landlord had already removed defects complained of, and, through his plumber, had undertaken to remove further defects complained of, it would be an unwise proceeding to leave the house and give the landlord no opportunity of removing the defects. As it was proved that the plaintiff's outlay amounted to 170*l.*, the Sheriff considered that 200*l.* was a fair amount to award. But if money could be any compensation for his losses plaintiff should have had the amount he claimed, which was not excessive.

It was at one time doubted by archaeologists whether in Egypt a Stone Age existed as in more northern regions. The paper which was read before the Society of Antiquaries of Scotland would of itself be enough to support the affirmative. Mr. FINLAY found examples of worked flints in the desert at Gebel-el-Gheir and other localities near Luxor. They are mostly flakes and chips, but among them are a very well-formed borer, a round edged scraper, several leaf-

shaped and triangular flakes that have been apparently used as side-scrapers, and one or two discoidal flints, the use of which is not obvious. A saw-toothed flake and a portion of a very finely-made instrument with extremely minute serration were obtained in the same locality, but not with the other flints. Much difference of opinion existed for some time after the first discoveries of worked flints in the Nile Valley, but there is now no doubt that along with the produce of the flint-working of comparatively recent times for the armature of the threshing sledges and gun-flints, as well as for purposes connected with ancient arts and ceremonial observances, there have been found in various localities along the Nile Valley a series of prehistoric flint implements corresponding more or less with those of Europe.

It is usually stated that GEORGE JAMESONE, who is known as the "Scottish VANDYKE" since WALPOLE's time, was born in 1586 in Aberdeen, that his father was an architect, and that he was a fellow-pupil with VANDYKE in RUBENS's studio in Antwerp. From the researches of Mr. J. R. LYELL among the Guildry Registers of Edinburgh, it would appear that the artist was apprenticed to an Edinburgh painter. The following entry has been discovered:—"1612, May 27.—GEORGE JAMESONE, son to ANDRO JAMESONE, burges in Aberdeen, enteris prenteis to JOHN ANDERSONE, paynter, for acht yeiris, conforme to their indentouris schawen, and payit of entre silver xiijs. iiij*d.*" In the margin of the register is "JAMESONE, paynter." In 1612 GEORGE JAMESONE's age would be twenty-six years, and after an eight years' apprenticeship he would have attained the age of thirty-four years, a rather late time to commence business. Then he must have spent some years as a pupil or assistant with RUBENS. If JOHN ANDERSONE, of Edinburgh, was a "paynter", of portraits, how is it that his name and works have been ignored? Some day an intelligible and consistent account of GEORGE JAMESONE may be prepared, but up to the present, inquiries seem to increase the obscurity around him.

So many people have an interest in the outlay on roads and streets that adjoin their houses, it is not right to allow the case Corporation of London *v.* GOODING to proceed without some notice. At the same time, as it is still *sub judice*, only the facts can be mentioned. Defendant is tenant under the Corporation of a laundry in the Cattle Market, Islington, and covenanted to pay for certain repairs to the road adjoining his premises. If any difference arose, it was to be settled by the certificate of the City architect. As the amount claimed appeared excessive, Mr. GOODING declined to pay. An action was taken in the City of London Court on February 22, but the deputy judge stopped the case and refused to allow it to go to the jury, on the ground that the certificates of the City architect were binding and could not be got behind. Defendant's counsel stated that he had abundant evidence to show that what was done to the street was not a repair but an alteration, caused by the Corporation improving neighbouring streets, their property. On Tuesday last, application on behalf of Mr. GOODING for a new trial was made in the Queen's Bench Division before Mr. Justice CHARLES and Mr. Justice HENN COLLINS. The application was granted, Mr. Justice CHARLES stating that there was a substantial case to go to the jury as to whether what was done was a repair or an alteration. Mr. Justice HENN COLLINS stated that the City architect's certificate would be swept aside should the jury decide that it was not a repair. The Corporation was ordered to pay the costs of the appeal.

THAT temporary hospitals can be costly is evident from the experience of Lower Tooting, where, without counting the site, the "Fountain" will entail an expenditure of 117,000*l.* on the ratepayers. It appears the cost per bed is about double what was paid for the temporary hospital at Tottenham. It is no wonder the Managers are taken aback. But henceforth there is to be no diminution of space, for they have resolved that in any ward or pavilion to be hereafter erected for convalescing fever patients, not less than 104 feet floor space, and 8 feet lineal space in the dormitories, and 60 square feet floor space in the day-room and dining-room combined be allowed for each patient.

BRONZE DOORS.

THE door is the weakest part of a building. Unless it has an area that will allow an individual of ample dimensions to pass through it is useless, and wherever friends can enter enemies are likely to follow. Windows are also openings, but they could be made secure by a variety of arrangements in days before patented appliances were introduced. Love, it has been said, laughs at locksmiths, and internal as well as external foes are often ready to demonstrate that a door is not an obstacle to ingress and egress. The history of the door becomes, therefore, a sort of comment on the strength of public and domestic government as well as of construction. Egyptian kings were aware they would not be allowed to rest in peace within pyramids, however colossal, unless the entrance to the tomb was concealed and placed at a height which could not be easily scaled, sometimes nearly sixty feet, with passages from the opening that were bewildering. Dr. DÖRPFELD'S plan of the palace at Tiryns suggests how roundabout was the course which had to be traversed before a visitor could have a chance of testing the strength of the entrance to the forecourt of a Greek country house. The effective doorway in many Mediæval churches would appear to be intended to admit little children instead of men and women; it is so small that a symbolical signification has been devised to explain its unfitness: the church door, it is said, was a compulsory reminder of the necessity of humbling oneself before entering the building. To gain admission to one of the Irish round towers it was necessary to have some means to reach a height of ten or more feet. Every visitor to old castles in Scotland is puzzled by the inhospitable character of the entrances. They are often so narrow in the North that jovial FALSTAFFS must have been excluded. The Scottish gentleman required at least two doors, "the outer of grated iron, the innermost of oak clenched with nails;" and sometimes, as SCOTT adds, "there was no stair at all, and the inhabitants ascended by a ladder from one storey to another." At one time the door in most parts of Europe was an example of military rather than civil construction. The old Eastern traveller who was amazed when he found there was a palace in Bokhara which had doors that were fixed back to the walls and were never closed for more than a century before his visit, could well declare he had seen nothing to compare with it in any other part of the world. In spite of the advance of civilisation, that sort of confidence has not yet become general. We may doubt whether it was ever witnessed in Asia. And yet if the etymologists are right the word originally signified an opening.

As a consequence of their insecurity doors were not only made strong enough to resist enemies, but it was found necessary to impart an expression of strength to them that all could understand. Wood was the material that men were compelled to employ, but it was made more resisting as well as more impressive by the application of metal. The strips from Balawat, in the British Museum, on which the victories of SHALMANESER II. are embossed, are substantial evidence to support the ancient traditions of the practice. They could not have added much to the resisting power of the gate they adorned, but they produced an effect that was as advantageous. The Mediæval architects were aware of the influence of the associations connected with metal, and the ramifications of hinges which are so often displayed on church doors subserve another purpose besides one of decoration.

It has been assumed that the ancient smiths were capable to do more than attach slips and plates to wood—that they could produce metal doors surpassing those which are being introduced into modern banks and repositories. Taken literally, such a description as is given of the Palace of Alcinoüs in the "Odyssey," with its brazen walls, golden doors, silver lintels, would be a proof of skill and wealth which are not common in our time. The account which HERODOTUS gives, as if he were an eye-witness, of the hundred gates of brass or bronze, with their entablatures and supports of the same metal, is also surprising. But what is probable is that the poet and the historian-traveller were like all the uninitiated in construction among their contemporaries, and confounded an outer coating with solid stuff. They were not the only victims to skill in veneering.

To investigate whether the ancients were competent to fashion immense pieces of metal-work is, however, outside our purpose. There is no doubt that they could make large figures and structures out of thick as well as thin pieces of bronze, cast or malleable plates, which they united by means of rivetting or by soldering, a process in which they were proficient. Recent explorations confirm WINCKELMANN'S conclusions when he said:—

We are informed by Pausanias that in the earliest ages, before the flourishing days of art, figures in bronze were composed of separate pieces fitted to each other and fastened by nails; as was a *Jupiter* at Sparta, the work of Learchus, of the school of Diponius and Scyllis. As this mode of casting statues was easier than the other it continued to be practised even in later periods, of which six Herculaneum female figures of and under the size of life are a proof, for the heads, arms and legs were cast separately, and even the trunk is not a single piece. These pieces are not united by solder—no traces of it having been discovered when they were cleaned—but are joined by tenons dovetailed in, which, from their shape , are called in Italy swallows' tails, a *coda di rondine*. The short mantle of these figures, which likewise consists of two pieces, a front and back, is joined on the shoulders, where it is represented as being buttoned. In this way the ancient artists strove to guard against defects not easily avoided in casting whole statues by a single operation.

Any one who has had an opportunity to observe the production of the immense statue of *Liberty*, which now is a landmark near New York, will be able to realise what can be done by piecemeal construction. With architectural work there would be less difficulty, and a very effective gate or door could be made up by a series of plain panels with borders on which a simple pattern was punched or engraved. When we read that STILICHO stole the gilt-plates from the door of the Capitoline Temple, and that another barbarian warrior carried off the gilt-plates from the roof, we must conclude that there was some affinity between the two classes of spoils. The surfaces of both may have been plain, or at least the plates on the roof were so, and they were valued by the vandals on account of the quality of the metal, which was supposed to be gold.

If we assume that metal plates were produced in quantities like encaustic tiles in our time, a vertical surface on one plane would form the most convenient base for their application. When closely and carefully laid, they would then be suggestive of a continuous plate of metal, and there is no doubt that sort of effect was sought after by the old builders. There seems to have been at all times an almost universal agreement that it is not fitting to ornament a door by engraved lines, as they would suggest a diminution of strength. Where, as in the old Byzantine door in the church of St. Paul outside the Walls, in Rome, the metal panels were engraved with figures and other pictorial subjects, the lines were afterwards filled in with silver. There are varieties enough among modern French doors, but it is rare that one sees a panel covered with incised ornament. The Romans were partial to applied mouldings and to metal bosses, for they enhanced the appearance of strength. As the people became effeminate, there was a desire for external aids to security, and hence chamber-doors were covered with bronze as well as those which opened on streets or grounds.

If doors are to serve only as defences, it would be logical to have as few planes as possible. The great door at Trani, which we represent this week, may correspond in treatment with much older examples. The panels could be plain, bevelled, or contain work in *repoussé*. As it is not easy to stretch metal in hammering, the relief in the Trani Gate is kept very low, but it is possible to obtain vigorous figures by the process. A door treated in a similar manner expresses its character, and, if detached from a building, its use can hardly be misunderstood.

From an early age, however, there was a desire to conceal the primary purpose for which doors were needed without diminishing the efficiency of them. SCOTT, with all his love for Border raids, does not forget to suggest that Newark's stately tower (with which his own race was associated) was never closed against the desolate and poor, although it often rolled back the tide of war. And if we revert to an earlier period, we cannot suppose that the beautiful ivory and gold ornamentation which was seen on the gates of the Temple of Minerva, at Syracuse, was entirely made up of elements that were intended to scare those who contemplated sacrilege. Numbers of Greeks found pleasure in writing about the beauty of those gates, and we may,

BRONZE DOOR, CATHEDRAL OF TRANI By Barisano.
(From a Photograph by Romualdo Moscioni, Rome.)

therefore, safely conclude they were not entirely suggestive of terror.

Whatever character was imparted to the bronze doors in Greek and Roman towns, it is never likely to affect the delight which is imparted by the Florentine gates of Ghiberti, or to diminish their inspiring power. Nothing is easier than to discover their weakness if tested by dogmatic theories. They are as defiant of accepted canons as Shakespeare's plays, but fortunately the world is not swayed by logic. Triqueti's gates in the Paris Madeleine are more consistent, but we doubt if one visitor in a hundred takes the trouble to notice them, while not one out of a thousand fails to enjoy Ghiberti's gates in the Florence Baptistery. It may appear a wrong to the earlier sculptor to couple such a name with his in a sentence, but one was as representative of convention as the other of liberty.

Ghiberti is not afraid to acknowledge that he executed his first gate under the influence of love of his art and discipline. It is evident that he was partly controlled by his respect for the work of Andrea Pisano, as if he asked himself how would that sculptor have treated the subjects if he could have had the benefit of the study of the antique like Ghiberti and his contemporaries? He tells us how he began with paintings of his subjects, and in his reliefs he endeavoured to at least equal what he had produced with the brush. In some panels he introduced nearly a hundred figures, and he did not hesitate to attempt architectural backgrounds and problems in perspective. He said simply, "I have represented the buildings as they would have appeared in their true proportions, and with so much truth that when they are regarded from a distance they appear to be detached from the ground." A door is an utilitarian object, but Ghiberti employed those with which he was entrusted as opportunities to display his art and to test the worth of his theories. That the metal-work is a protective fence is likely to be overlooked; such a purpose could be served as efficiently by the handiwork of a carpenter or a smith. Ghiberti felt he was employed because he was an artist, and as one he asserted the right to express his thoughts and realise his imagination. Neither the Signoria nor the Guild of Merchants, who conjointly commissioned him, are likely to be called to account in another world for their extravagance in setting up sculpture where plain boards would have served.

We must not expect that modern building-owners will often care to have bronze doors, but when one is discovered who can appreciate a work of the kind, it is to be hoped he will prefer the Florentine to the Trani precedent. The Liverpool Banking Company, when they approved of the experiment of Mr. Caröe and Mr. Stirling Lee, were as liberal as the old Florentines. St. John is not dominant in Ghiberti's gates, and the portraits that project are not Biblical. At Liverpool there is no puffing of commerce or banking, and the representatives of the fraternal spirit—David and Jonathan, Achilles and Patroclus, Castor and Pollux, Roland and Oliver—are not, we presume, portraits of the directors. The lower part is architectural in character, with the mouldings and details that can only be perfectly wrought when metal is used. The Adelphi Gate will bear comparison with the two which were designed by Alfred Stevens and Godfrey Sykes, and it is to be hoped that worthy companions will be found for them. A country in which so much metal is produced should be able to show all kinds of applications of the material.

EVOLUTION IN DECORATIVE ART.*

IT is my object this evening to describe in a brief and general way some of the changes undergone by art designs in their treatment, especially for decorative effect, and the causes which have brought about these changes, as illustrating the very many influences which affect the developmental history of patterns and designs generally. I shall also give a few instances in which the actual origin of certain ornamental designs can be ascertained and accounted for.

As, in the course of a single lecture, I can only hope to treat of my subject in a very general and cursory manner, it is necessary that the examples selected should be as simple as possible, and with this object in view I have chosen illustra-

tions for the most part from the art of the less cultured races of mankind, as the lower we go in the scale of civilisation the fewer agencies do we find affecting the growth of any particular art or industry, and consequently there is a diminished complexity with which to deal.

Before passing on to the main subject of my lecture, a few words regarding the early history of the art of design may not be amiss. It is when we endeavour to form conclusions as to the probable origin and early developmental stages of art that we are brought face to face with the consideration of the relationship of anthropology to archæology. These sciences are very closely allied; indeed, the two studies can hardly exist apart from one another, as each serves at times to elucidate points which are obscure in the evidence at the disposal of the other. The dominant idea in the two sciences is the same—to trace a continuity in the history of the human race, and to endeavour to form an unbroken chain of evidence to show the successive changes whereby man has arrived at his present state, both physical and mental. Anthropology, as dealing principally with the recent races of mankind, offers to archæology facts culled from peoples in various conditions of culture and physical development, peoples which variously exhibit, we believe, conditions of progress arrested or retarded at different stages in the general progressive evolution. The present is offered in explanation of the past, the living as representative of the dead. In the study of the history and gradual development of the art of design, more particularly in its earlier stages of growth, we feel very specially the need of something beyond the evidence supplied by archæology. This in no way gives an unbroken continuity, and of man's earliest efforts in plastic and graphic art we have no actual trace remaining. The earliest period at which we meet with relics of man's attempts in this direction belongs, it is true, to a relatively very remote age, when the mammoth and reindeer were conspicuous features in Central France, and the climate there was of that rigorous kind which suited these representatives of an Arctic fauna. Remote as was this so-called "Cave Period," we find from the associated relics of man's handiwork that human culture had in many ways already reached a considerable degree of development, that man already displayed not only ingenuity and dexterity in the manufacture of the implements of his everyday life, but also a skill and taste of no mean order in the art of design, as evidenced by his application of decoration to his implements. The often extremely clear and realistic sketches of the more characteristic animals, engraved upon pieces of horn, bone or ivory, or carved in complete relief as ornamental handles for horn daggers, show not only a keen observation and accurate knowledge of the animals portrayed, but also a considerable experience and adroitness in the use of the burin and the carving-tool of the period, even though these were but flakes of flint and such rude appliances. It is quite evident that the beginnings of art are not to be found here. In the still earlier period of the river drift gravels we find no traces of art-work amongst the remains of human industry preserved, and we are therefore unable, from actual relics of antiquity, to trace the history of this branch of æsthetic industry back beyond a period at which it had already reached a high state of development, which implies a long ancestry in the remoter past, of which we as yet know nothing.

In view of the lack of any archæological evidence as to the origin of the early development of the art of design, if we turn to the study of the living races of man we find that we may gather much that is suggestive and capable of throwing light upon the obscurity, and we are able to form some conclusions as to the probable succession of progressive changes undergone by art in the days of its infancy. In the life of the lowest or least cultured modern savage races we see reflected to a great extent the condition of primeval man, as has been ably pointed out by General Pitt-Rivers,* and a study of the condition of art among modern primitive folk cannot fail to illumine the obscure points in its actual early history in prehistoric times.

In examining the handiwork of these people, it becomes evident that their ideas are very largely derived from nature's suggestions. The forms of their implements are, for the most part, natural shapes, but slightly improved upon or adapted. We see also how readily curious or unusual natural objects are appreciated and valued and made to serve usually as charms, as being endowed with magic properties. In accordance with the "animistic" ideas of primitive man, those objects in nature which bear an accidental resemblance to some familiar thing, say an animal or the human form, are especially valued as having a kind of physical sympathetic relationship with the object whose form they simulate. One may readily believe that the rudiments of the art of æsthetic design are to be traced to the appreciation of the unusual in nature, associated largely with the primitive beliefs in the magical properties of such peculiarities. Strange shapes were eagerly sought for, and carefully preserved and valued according to the degree to which they were uncommon,

* A paper by Mr. Henry Balfour, M.A., read before the Applied Art Section of the Society of Arts, on Tuesday, April 10.

* "Primitive Warfare," *Journal of the Royal United Service Institution*, xi. No. 47.

or the extent to which they showed resemblances to familiar objects. In the Pitt-Rivers collection at Oxford is an Australian boomerang of yellow wood, cut out in such a manner as to exhibit along the central line a row of very dark natural knots in the grain, which occur at fairly regular intervals, and form an effective, though purely natural, decoration. Until recently natural boulders of peculiar shapes, especially if in any way suggesting the human form, were objects of worship to the Lapps. Of the many charms whose virtue lies in their resemblance to certain objects, I may mention the two-hooked *martynia* seed capsules, whose resemblance to the head and fangs of a poisonous snake has caused them to be used as charms against snake bites. In much the same way the kernel of a kind of chestnut—native of Demerara—(*Ophiocaryon serpentinum*), which resembles very curiously a little coiled-up snake, was assumed by the early colonists to be effective as an antidote to snake poison.

This merely "appreciative" stage can only be regarded as introductory to the origin of art, the actual germs of which appeared in the next stage. This new stage was arrived at when first the natural peculiarities or resemblances were slightly intensified by the application of artificial means to increase them. Where, for instance, an accidental resemblance to an animal's head was found, it would have been seen that the addition of a spot at the right place to represent an eye would greatly increase the resemblance; or by blackening the nodes on a reed stem, the decorative effect already suggested by the regularity with which these are naturally disposed would have been heightened. The first application of such slight improvements would not have required a great mental effort, and would have formed a perfectly natural sequel to the appreciation of the purely natural effects. As belonging to this "adaptive" stage, I may cite, as examples from modern life, the gnarled roots which the Chinese value for the weird resemblances which they sometimes bear to animals, and which the people touch up here and there in order to make the resemblance stronger, thereby producing very grotesque monsters. The mandrake roots sold in the Asia Minor bazaars as charms, by virtue of their resemblances to the human form, are, in reality, for the most part partly carved with a knife to enhance their value in the eyes of the ignorant buyers, who believe that they are of purely natural growth. I have a sealing charm which was carried by a Haida Indian, of Queen Charlotte Island, when seal-hunting; this is merely a natural pebble of elongated shape somewhat resembling a seal in outline. The hunter, in order to increase the resemblance, and, consequently, the value of his charm, added a circle, with a dot in the centre to represent the eye, on each side, and scratches to indicate the mouth.

In the earliest days, no doubt, the additional artificial touches were but few, and the natural effects but slightly increased, but as time went on the increasing use of artificial means to improve upon natural peculiarities doubtless led gradually to a stage in which the whole effects were produced artificially, and it was found that the effects could be thus copied. This brought the development of art to a definite "creative" stage, and, once man found that he could produce at will decorative effects or representations of objects, the real starting-point of art industry was reached, and a very wide field for the development of his æsthetic tendencies and imitative faculties was opened out. The magic powers of nature's accidental portraits were transferred to the artificial representations, though the peculiar natural forms were and are none the less eagerly sought for and valued as the more potent of the two kinds. At first, no doubt, it was nature's decorative patterns which were copied, before man more and more emancipated himself from his "mistress in art," and proceeded upon somewhat more original plans of his own. The three stages, appreciative, adaptive and creative, seem to follow one another in a perfectly natural sequence, and there can be little doubt that these represent the successive epochs in the early history of art, and our knowledge of modern savage life does, I think, fully bear out the probability of such a sequence, and help to establish this in relation to primeval man in his early crude efforts in the production of objects of art.

So far as representations of objects or portraiture are concerned, it would seem likely that graphic art was derived as a later development from plastic art, though this is largely a matter of conjecture. We know that solid shapes appeal more readily to the lowly cultured mind than do designs representing the same objects in the flat, and we can readily imagine a gradual evolution of graphic representation from the application of lines and fine incisions to express important details which were lacking in the solid representations of objects. The freer use of lines as a means of expression would in time have led to the discovery that the entire object could be represented in this way upon a flat surface, and with less labour than was required for carving or moulding figures in complete relief. In illustration I will take a case from the art of the Eskimo, though this in no way pretends to be actually a primitive transitional example, as the art of these people, both graphic and plastic, is highly developed. The little ivory thing is

carved into a shape representing the head of a polar bear, the details not expressed by the shape being added by means of supplemental lines—thus, the mouth, eyes, ears, &c., are supplied. On the reverse side we see that the bear's head has given place to a representation of a seal; but the shape of the piece is not so well adapted to express the outline of a seal, and we see that the supplemental lines have to convey more in this case than in the other; the lower part of the body and the limbs are drawn in, as they are not otherwise suggested.

How far the application of colours to flat surfaces influenced the early development of graphic art, as applied to outline representations of objects, it would be hard to say. We know that the use of colours in painting for decorative purposes was of great antiquity, and no doubt the habit of giving patches of colour definite shapes had some effect in assisting the growth of outline drawing, but into this I cannot now enter.

The few remarks which I have been able to make upon the general subject of the early history of plastic and graphic art, from a general standpoint, must necessarily convey very inadequately the points upon which I have touched. In dealing with so wide a subject it is unavoidable that one's remarks should appear sketchy and possibly unconvincing, but I am anxious to-night to give some account of the origin of individual patterns and art forms, and to put before you some of the factors which create changes in designs and cause these to be unstable and ever changing.

If I were to say that copying is one of the chief agents in creating variations in designs, I might be accused of dealing with paradoxes, but I should be quite justified in making the statement, and, as a matter of fact, I do make it. Man is nothing if not imitative, and the art of copying is perhaps one of his most useful accomplishments. But, even where every effort is made to produce an accurate copy of an original, in no case is the result an exact facsimile of the object copied. In estimating the value of copying, one must not undervalue the individuality of the artist. No two will copy an object in precisely the same manner and with the same result; there is always the "personal equation" to be reckoned with. In some cases this is very marked. Sir Robert Porter bitterly complains, in his "Travels in Georgia," of the inaccuracy with which sculptures were copied by archaeologists, and he gives in his book a plate showing copies of the same bas-relief by three different explorers. The results are so absurdly different that it becomes a compliment to Sir Robert Porter when we take his word for it that they are really intended to represent the same sculpture. It is certain that, if the ancient Persepolitan sculptor were to see them, and was able to recognise one of the designs as a copy of his own bas-relief, he would utterly refuse to hold the same view with regard to the other two copies.* This is, perhaps, an extreme case, but it is useful as illustrating the effect of the individual eye and hand in copying.

Suppose, however, instead of all being taken directly from an original, the copies are made successively one from another, the last copy of the growing series being in each case the model for the next. The changes produced by this process of successive copying are often very astonishing, and it would be difficult to over-estimate the importance of this process as an agent in producing variations in designs. This any one can try for himself; it is only necessary to give some design to be copied by a person whom I will call A, give A's copy to B to reproduce, B's to C, and so on, and it will be seen that while each may be a fairly good representation of the one before, as the series grows a marked difference between the original design and the last of the successive copies has arisen. The number of copyings required before any marked change is noticeable will, of course, depend upon the degree of skill of the copyists. A sketch representing a snail crawling over a twig, which I gave out to, for the most part, fairly unskilled hands to copy, successively went through a series of rapid changes, and became, in the course of some fourteen copyings, a kind of bird-like figure. The shell of the snail gradually left its owner, and crawled up the twig; the end of the twig became the head of the bird, the growth-rings becoming the eye; the eye-stalks on the head of the snail were metamorphosed into the forked tail of the bird. After the twelfth copy the design was copied upside down, as it looked more realistic so, and thus the bird came into being. Though the copies are not good ones, there is no striking difference between any two adjacent ones; but, nevertheless, there is no resemblance whatever between the first and the fourteenth, and, if seen apart from the series, no one would suppose them to be related.

In a similar manner a sketch of a Greek warrior became gradually, after nine or ten copyings, one representing a female figure, the collar-bones of the warrior having drooped more and more into a V-shape, till they became the edges of a cloak thrown loosely over the woman's shoulders, the warrior's muscles becoming folds in the cloak.

It may be urged that in skilful hands very little change

* The copies shown in the plate are by Chardin in 1674, Le Brun in 1704, and Niebuh in 1765.

would be noticeable, but I will give an illustration to show that even when skilled engravers have been the reproducers of a design, remarkable changes are apt to occur when the design is copied successively. The series which I give is one of four only, an original and three copies. The designs represent a ceremonial dance of the natives of Virginia in the sixteenth century. In each case I have only given a portion of the plate, showing a few figures only. The first, a photograph of the original water-colour drawing by John White, dating towards the end of the sixteenth century. The second from an engraving in De Bry's edition of Hariot's "Description of Virginia" (second or third edition, 1634), this having been taken from White's drawing and reversed. The third from Lafitau ("Mœurs des Sauvages," II. pl. 6, 1724), copied from De Bry's plate and reversed back again. The fourth from an engraving in Sir John Lubbock's "Origin of Civilisation," p. 248 (1875), copied from Lafitau. Now let us look at the figure in the centre of the original drawing, slightly turned towards the right. A gourd rattle is held in the left hand for shaking as an accompaniment to the dancer. This we see plainly in De Bry's reversed, but excellent, not to say idealised, engraving. In Lafitau's engraving the gourd is still there, but badly represented, very darkly shaded on one side, with but a faint line to represent the outline of the gourd on the other side. This faint line escaped the notice of Lubbock's engraver, and he represented the figure as clutching the shading only, literally "grasping a shadow," most unsatisfactory for the dancer. The figure dressed in leafy bough in the original holds a small branch in his right hand; this appears as a gourd rattle in the copies; perhaps this compensates somewhat for the loss of the other dancer's rattle. Such changes as these are, I supposed, considered permissible under the plea of "engraver's license," but when the letterpress, too, becomes bitten with the same craving for change, and endeavours to follow and keep pace with the erratic metamorphoses of the illustrations, it is, perhaps, going a little too far. The upright columns, which in the entire design can be seen standing in a circle, are described in Hariot's original work as "posts," and in De Bry's Latin translation as "tigna." They are clearly of wood, and are so represented in De Bry's engravings, where very evident knots in the grain are seen; these are hardly shown in Lafitau, and his careless representation has led to the materials of the posts being changed in the later description. Sir John Lubbock has, in fact, petrified these posts, and we read in his reference to the illustration as follows:—"It is very interesting to see here a circle of upright *stones* [my italics], which, except that they are rudely carved at the upper end in the form of a head, exactly resemble our so-called Druidical temples." I would draw special attention to the fact that all the changes mentioned in this case have occurred in the course of three successive copyings only. One shudders to contemplate what would have occurred in fourteen or twenty. These examples will suffice to show how very great may be the changes wrought unintentionally through the agency of successive copying, and how very necessary it is, where possible, to go direct to the original source, whether for illustrations or descriptions. The rate at which change will take place varies necessarily with the skill and care exercised by the artists and the relative difficulty of the material and other details of circumstances, but, whether the copyists be inexperienced and unskilled, or whether they be the leading artists of the day, the changes would still be seen, though in the one case a longer series would be required to effect any radical change in the design, the difference between any two adjacent copies being far slighter in the case of skilled artist's work. Where designs have been reproduced from memory we can readily understand that still more marked variations from the original will occur. Such changes as are produced unintentionally through carelessness and the impossibility of copying quite accurately, are due to what I have called unconscious variation. But active as is this process as a factor in producing change, it is usually accompanied and the change is accelerated by the still more active and unrestrained agent, conscious variation. In the reproduction of ornamental patterns there is often a desire to vary or to improve upon the design copied. The motives for this intentional variation are many and various, and while sometimes the changes are merely to suit the individual taste or are due to caprice on the part of the artist, at other times they are of a more strictly utilitarian nature.

(To be continued.)

The Council of the Leeds and Yorkshire Architectural Society for the coming year will consist of the following members:—President, Mr. E. J. Dodgshun; vice-presidents, Mr. W. Watson and Mr. W. Carby Hall; hon. treasurer, Mr. W. H. Thorp; hon. librarian, Mr. W. H. Beevers; hon. sec., Mr. F. W. Bedford; ordinary members, Mr. H. B. Buckley, Mr. J. N. Greaves, Mr. W. A. Hobson, Mr. G. F. Danby and Mr. James Ledingham; auditors, Mr. A. E. Kirk and Mr. H. S. Chorley.

TESSERÆ.

Perugino at Panicale.

ON one of the wooded hills rising above the lake of Perugia stands the small town of Panicale. Its half-ruined walls and towers show that it was a fortified post of some importance during the Middle Ages. Away from the high roads leading to the principal cities of central Italy, it is seldom visited by the traveller, who would scarcely find in it the miserable shelter of an Italian "osteria." Yet, like almost every town and hamlet of this favoured land, it contains works of art such as elsewhere would render a city famous. Outside the walls, on an olive-clad eminence overlooking the town, is a convent of nuns. Attached to it is a chapel dedicated to St. Sebastian. The wall behind its high altar is covered with a fresco representing the martyrdom of the saint. It is the work, and may be ranked amongst the finest, of a painter who by his genius and the influence he exercised upon his great contemporaries, forms an epoch in the history of art—Pietro Vannucci, or as he is more commonly called, from the city in which he principally laboured and founded his school, "Il Perugino." This noble work, although mentioned in most lives of the painter, is unnoticed by his first biographer, Vasari. It has consequently been overlooked even by those who have made the history of the art of his period a study. Of the numerous works of Pietro Perugino there is scarcely one that displays to greater advantage the peculiar characteristics of the master, the delicate tenderness of his colouring, the grace, verging on weakness, of his forms, the exquisite purity and sentiment of his heads, the general correctness of his drawing, and his somewhat scattered composition. It has all the best qualities of the Umbrian School, inherited by Pietro from his first instructors in the art, Benedetto Bonfigli, of Perugia, and Niccolò Alunno, a native of Foligno, whose altar-pieces, remarkable for their glow of colour and the simple beauty of their holy groups, still adorn the churches in the valley of the Tiber. But in it Pietro shows at the same time that he has been imbued with the spirit of that great school which flourished in Florence and whose teachings he had early sought. It has less of his weakness and mannerism and more of his strength than most of his paintings, displaying those qualities which the genius of his immortal pupil at once culled from his works. The martyr occupies the centre of the composition, and forms the principal object in it. He is bound to a porphyry column raised on a pedestal. The exquisite proportions of the figure, the admirable delineation of all its parts, show the study devoted by Pietro to the human form. The tender expression of devotion in the upturned head, slightly inclined over the right shoulder, is peculiar to the school, but does not in this instance degenerate into affectation. The painter has united in this beautiful figure without exaggeration the utmost grace with the deepest religious feeling. A more perfect and touching representation of the Christian martyr could not be conceived. On the pedestal supporting the martyr is inscribed the name of the painter, and on the pilasters of the arcade the date 1505. Pietro was then in the fifty-ninth year of his age. About ten years previously he had settled in Perugia, after his fame had been established by the execution of great works in Florence and in Rome. The city had conferred upon him the right of citizenship, and had even raised him to the dignity of one of its ten "Priori," or magistrates. During these ten years he had painted his finest pictures, amongst them the altar-piece for the Certosa of Pavia, now in the National Gallery. In Perugia and the neighbouring towns he decorated the principal buildings and churches. The celebrated frescoes in the "Cambio," or Exchange, and the adjoining chapel were executed in 1500; the *Adoration of the Magi* at his native place, Citta della Pieve, in 1504. His powers were at their height when he painted the *Martyrdom of St. Sebastian* at Panicale. At this time the fame of his school had spread through Italy, and had brought to him his most distinguished scholars, L'Ingegno, Lo Spagna, Tiberio d'Assisi and many others, whose paintings have been so frequently confounded with those of their master. They aided him in his great undertakings, and rendered them perfect and complete in their most minute details. Before he executed the fresco at Panicale, Raphael had already left him, and was probably painting at Florence or Siena. Consequently, there are no traces of his pencil in it. It is important to mention this fact, as there are parts of the picture which might otherwise be ascribed to that great painter. There is no record of the sum received by Pietro for the Panicale fresco, but there is a curious correspondence still preserved in the archives of Perugia relating to it. From these letters it appears that in the year 1507, or two years after its completion, the people of Panicale sent an emissary to the painter, requesting him to lend the commune some standards of silk painted with figures, to be carried in the annual procession of the "Corpus Domini." Pietro offered to paint fourteen expressly for the festival, on condition that they should be returned unless the balance of eleven florins, owing to him for the fresco of the *Martyrdom of St. Sebastian* were pre-

viously paid. The Panicaese accepted the offer, and a receipt, dated September 1 of the same year, shows that they paid the money and kept the standards. This is an instance, among many that could be cited, of the liberality of a painter whom Vasari accuses of meanness.

The Architecture of Madrid.

Madrid is, by some centuries, the youngest capital in Europe, St. Petersburg excepted, as it cannot be said to have been founded before the sixteenth century by Charles V. It in consequence is deficient in ancient architectural monuments, in Roman, Moorish, Gothic, or even Cinquecento art. It possesses no Notre Dame or Louvre and Tuileries, like Paris. It has no Westminster Hall, Westminster Abbey, no Tower, no Whitehall Banqueting House, like London; and is unfortunately rich in Rococo, which was the reigning style at the earlier period of its erection. It is, besides, the smallest capital of a great nation in Europe. Nevertheless, it has some architectural features superior at least to London. We have no street in London, nor yet, indeed, is there in Paris, which can vie with the Calle de Alcalá in its noble expanse and its varied succession of buildings of sumptuous or stately architecture. There was a sort of reaction in the architectural taste of Spain before the middle of the eighteenth century, the first native who opposed successfully the Churrigueresque style being Ventura de Rodríguez; he fortunately, with his followers, led back to a more severe and correct style of design, which became extremely popular and beneficial to the architectural display of Madrid. He was the founder, in fact, of the modern architectural taste of Spain existing to this day. No metropolis in Europe presents a royal palace which, taking all things into consideration, can vie with that of Madrid. It was erected for Philip V. by Juvara, a Sicilian, and Jachetti, a Turinese, to whom with Sabatini, also a Sicilian, Rodríguez and Villanueva, Madrid owes her best architecture. Its style is Italian; it is square, each of its fronts being 470 feet in length by 100 feet high. It is built of white stone, with a rustic base of granite. It encloses a magnificent court, and is of itself a building of the utmost importance; but there is an inexpressible charm given to it by its extraordinary site, and that site the more extraordinary as being connected with a busy and populous city. This sumptuous pile towers over a country grand in its wildness, and closed by the magnificent range of the Guadrama mountains. It forcibly recalls to mind some of those finest works of Claude Lorraine, where noble and elegant fabrics of Italian architecture are surrounded by and contrasted with nature and her grandest features in the expanse of the boundless sea, or the vast and luxuriant wilderness closed by the rolling Apennines, forming a whole fraught with poetry. The most considerable work of Villanueva is the Museo (the National Gallery) of Madrid, beautifully situated on the Prado. It is of red brick, ornamented with granite. The principal façade—although in some respects open to criticism, as being flanked by two projections in the manner of bastions, tending to injure the harmony of the outline—is a work of considerable merit. In the centre is a hexastyle portico of Doric, flanked by two Ionic colonnades of incomparable beauty, and the Ionic temple which forms the lateral, *i.e.* the principal, entrance is unrivalled in beauty and fitness. The vast circular hall of entrance, from which open the entrances to the various galleries or schools diverging from it, is one of the noblest and most appropriate of designs.

The Interior of St. Peter's, Rome.

On entering St. Peter's every observer is astonished that its dimensions appear so much less than they really are. This has been attributed to the justness of the proportions of the building, and strangely enough has been adduced as a merit. On a very little consideration this must appear a most extraordinary error. If indeed it be owing to the proportions of St. Peter's that it appears less than it is, this must be considered as a proof, not that its proportions are exactly what they ought to be, but that there is something wrong about them; for its magnificent dimensions are generally and justly regarded as one fit cause of our admiration, and therefore that must be thought a defect which conceals their immensity. If, on the other hand, it be a merit in the proportions of St. Peter's that they diminish to the eye its real size, then that size must be a defect, and the expense and labour of producing it must have been more than wasted. In truth, however, the justness of the theory which attributes to the general proportions of a building, unassisted by its darkness or lightness, the power of diminishing or augmenting the whole magnitude of a building may be doubted. The true cause of the apparent diminution of St. Peter's, in part at least, may be the great magnitude of the numerous statues in the church. These are, in fact, all colossal, and as our eye is accustomed to statues more near the size of life, they serve as a false standard by which we measure the church in which they stand. Statues of white marble have also, from their brilliancy of colour, the appearance of being much nearer to the eye than they really are, which must of course diminish their apparent magnitude and render the scale afforded by them still more fallacious. The great light of

St. Peter's, especially when contrasted, as it will be involuntarily by all foreigners, with the gloominess of their own Gothic cathedrals, contributes to the same effect of reducing its seeming dimensions. On the whole the interior of St. Peter's is very handsome, but it is to be regretted that the entablature over the pilasters of the nave is so much broken, and that the beautiful frieze, which is over two of them, has not been continued. As it is, it only serves to make the deficiency more striking. There is also too great a mixture of differently coloured marbles in the arches that support the nave, and the capella papale is certainly a disgrace to so noble and generally simple an edifice. It is a singular circumstance that the tall fluted and reeded Corinthian pilasters between the arches of the nave are only painted in imitation of white marble. The retrenchment of some of the superfluous ornaments of the church would probably have sufficed to have made them what they pretend to be. The cupola would be rendered more beautiful by continuing the entablature over its pilasters, but it would perhaps add too much to the weight for the security of the building. After all, the continuance of an internal entablature is of much less importance, as, in truth, any cornice within a building is rather a solecism, it being properly and originally the projection of the roof, and therefore Milizia suggests that it would be better in the interior of a building to omit the cornice altogether, making use of a simple frieze.

Florentine Associations.

Though few societies have had a Thucydides to write their history, or have had their daily life stereotyped by writers with the dramatic power of Plato and Demosthenes, any attempt at really comprehending Athenian society must fail. But in the case of Florence this is possible, so far as it can be possible with any community a few hundred years removed from our own. Live in Florence for a year, saunter daily in the Piazza della Signoria, worship in St. Mary of the Flower, traverse early in the morning the streets of the Mercato Vecchio, and if you have a good knowledge of Italian and an affable manner you will soon feel that you would be perfectly at home in the Florence of Corso Donati. The Siennese a few years ago were unwilling to come to Florence lest they should encounter the memory of the defeat of Montaperti. The name Cerretiere still bears witness to the loathing and abhorrence felt for the traitorous creature of the Duke of Athens. The ground on which Savonarola suffered martyrdom was till the last century strewn with flowers on every anniversary of his death. The same old customs and ceremonies are still kept up on the same days, except that St. John's Day has given way at last to the festival of Italian Unity. Indeed, every step a Florentine takes through his native city reminds him of some event in his country's history. There is scarcely a church or a palace or a convent or even a room where anything important in Florentine history was transacted which does not still remain in its original state. To one standing on the Piazza, which after several changes has returned to its original name, the wall of the public palace marks by its distorted outline the unholy ground on which the abode of the Uberti stood—those traitors to the cause of their country whose treason was scarcely atoned for by the noble firmness of Farinata. The post-office by its name, *Tetto dei Pisani*, recalls the temporary defeat of that great city which was still for many years to be a rival to Florence. The public palace itself still contains the room in which the council of the signory debated for two hundred and fifty years the affairs of the republic, the chapel where the *émeute* of the Ciompi was first divulged, and the "little chamber" in the tower where Cosmo dei Medici was imprisoned—an event which was the beginning of the end of the republic. The church which Dante called "*il mio bel Giovanni*" remains as beautiful as when he looked upon it from the stone which still marks the place of his meditations. At the doors are the porphyry columns which Pisa gave to Florence in the days when they were not sufficiently equal to be rivals. These instances might be multiplied indefinitely.

Ammonius Saccas (A.D. 175-250) on Architectural Logic.

In general the end of theory is the beginning of practice, and so, reciprocally, the end of practice the beginning of theory. Thus, for instance: an architect, being ordered to build a house, says to himself, I am ordered to build a house, that is to say, a certain defence to protect against the rains and the heats. But this cannot be without a roof or covering. From this point therefore he begins his theory. He proceeds and says:—But there can be no roof if there be no walls, and there can be no walls without some foundations, nor can there be laid foundations without opening the earth. At this point the theory is at an end. Hence, therefore, commences the practice or action. For first he opens the earth, then lays the foundation, then raises the walls, and lastly puts on the roof, which is the end of the action or practice (but beginning of the theory), as the beginning of the practice was the end of the theory.

NOTES AND COMMENTS.

A CONTRACT-DEED relating to the building of the parish church of Oldham, and dated November 4, 1476, was exhibited at the last meeting of the Lancashire and Cheshire Antiquarian Society. Mr. J. P. EARWAKER, in introducing it, said the contracting parties were Sir RALPH LANGLEY, the rector of Prestwich, and three masons. The sum to be paid for the body of the church was 28*l.* 6*s.* 8*d.*, an amount which was significant of the high value of money at that date. The work was to be done mainly by the contractors' own hands, and 2½ years were allowed for its completion. In case of disagreement other masons were to be called in, whose decision, given according to "faith and conscience," was to be binding upon both sides. Contract-deeds relating to buildings are very rare. This particular one is in English, and contains some uncommon words. The church stood till 1824, when it was taken down and rebuilt.

THE competitors who sent in designs for the Hammer-smith Town Hall were mainly local architects, viz. Mr. T. GARRATT, Mr. H. R. GOUGH, Messrs. ISAACS & FLORENCE, Mr. G. W. MOUNTFORD, Mr. W. G. PERKINS, Messrs. PUGIN & PUGIN and Mr. J. H. RICHARDSON. In his report on the designs, Mr. EMERSON stated that plan A (Mr. RICHARDSON'S) was undoubtedly the first in order of merit and best complies with the conditions. The town hall committee have recommended the adoption of the design, subject to such modifications as may be required by the London County Council and the Vestry, and that the cost will be about 25,000*l.* The vestrymen are almost equally divided about postponing the time for arriving at a decision, and it was agreed that the proposal should go back to the committee for a fortnight. The successful design is Renaissance in style, freely treated, and would be executed in red brick with Portland stone dressings. The roofs would be covered with permanent green slates. Blue lias concrete, hard stock bricks for general work, blue bricks for piers carrying great weight, built in cement. Marble mosaic floors are designed for corridors, and hard York stone for all stairs. The timber for carpentry would be the best Baltic Memel fir. It is proposed to execute the work in a plain substantial manner but with an eye to artistic effect.

THE palace at Laeken, near Brussels, which was in part destroyed by the fire on January 1, has been carefully restored and where necessary rebuilt. The building is not ancient—for it only dates from 1782—but it has acquired historical interest. It was constructed as a summer residence for the Austrian Governors of the Netherlands. The Archduke ALBERT OF SAXE-TESSCHEN, who held the appointment at the time, was an amateur, and he drew designs for the palace which were put into a definite shape by MONTOYER, the architect. The style was Classic, the portico had Ionic columns, and in the pediment was a relief by GODECHARLES representing Time presiding over the hours, days and seasons. The palace was acquired by NAPOLEON, who presented it to JOSEPHINE. It was there he signed the declaration of war with Russia, which led to the downfall of the Empire. Eventually it came into the possession of LEOPOLD I., who preferred it as a residence to the palace in Brussels. The present King of the BELGIANS has, like his father, laid out large sums on the improvement of the place. The restored building differs little from its predecessor, except in additions for the comfort of the residents. The grounds were originally laid out to resemble an English park, and during the coming summer they are likely to receive the admiration of thousands of visitors.

WHAT are "les hautes études architectoniques"? The phrase was undoubtedly derived from the French circus, but what it signifies in building is not easily defined. Every architect naturally attaches importance to his humblest work, and it is not generally admitted that costly structures alone are entitled to be considered as examples of high art or of purity in style. The difficulty of defining "hautes

études" has caused the Prix Duc, which is worth 150*l.*, to be going a-begging. There is more or less presumption ascribed to any architect who sets himself up as a competitor for the prize, and in consequence, this year there is not one eligible applicant. The late M. Duc was, we believe, a humourist, and disposed to enjoy the weakness of his contemporaries. He may have instituted the prize for the gratification of men like himself, who could enjoy the professional comedy in succeeding ages. There is, however, a possibility that the character of the prize will be altered. A sum of 150*l.* a year is too large to be left unproductive in France, and accordingly, at the sitting of the Académie des Beaux-Arts on Saturday, M. ALFRED NORMAND inquired whether some modification of the conditions could not be arranged with M. Duc's family. That is the first step towards a change. It is possible to pay too much for a good joke, and it would be better to apply the money to another use than in the creation of a band of men who can be chaffed by their fellows. But the surest way out of the difficulty would be to take a hint from London and assign the Prix Duc to painters.

ALTHOUGH the World's Fair, at Chicago, has been relegated to the region of antiquity, the French Government have not forgotten the services of the French artists who have contributed to it. The following have been elevated to the rank of officers of the Legion of Honour:—M. JEAN BÉRAUD, painter; Mdle. ROSA BONHEUR, who is the first lady to attain this distinction; MM. LHERMITTE and LUMINAIS, painters; BOUCHER and MARQUESTE, sculptors; LEOPOLD FLAMENG, engraver; and MASSIER, artist in pottery. The following chevaliers are also appointed:—MM. AUGUIN, JEAN BENNER, VICTOR BINET, BORDES, BROUILLET, BULAND, DELACROIX DE RICHEMOND, GUILLON, CLAVEL or IWILL, MAURICE LOLOIR, AIMÉ PERRET, RENOARD, painters; DAILLION, LABATUT, LOMBARD, sculptors; BRUNET-DEBAINES ET LÉVEILLÉ, engravers; FRANTZ JOURDAIN and SANDIER, architects; TAXILE DOAT, superintendent at Sèvres; MUNIER, superintendent at the Gobelins; LACROIX, superintendent at Beauvais; BRATEAU, goldsmith; JOSEPH CHÉRET and DELAHERCHE, artists in pottery; and RAULT, carver. It will be observed that among so large a number of artists only two architects have been recognised.

IF all the opponents of the London Streets and Buildings Bill are to be represented by counsel, the Parliamentary Bar will have no reason to complain of the present session. The sign-painters of the Metropolis are among the latest who have taken up arms against the proposals of the County Council. Their ground of complaint is section 176, which prescribes that "any boards, frames, plates, tablets or other like structures, attached after the commencement of this Act to the external walls of buildings for the purpose of advertisement, shall be constructed of fire-resisting materials throughout." It appears that within the metropolitan area there are about two hundred masters, who are supposed to employ a thousand men as painters, glass-writers, carpenters and labourers. That number may not appear of much importance in Spring Gardens; but the industry is important, especially as it is one of those in which apprenticeship is needful. It is not very clear how fires can originate in wooden signboards, and if the fire arises within a building, it must have made some progress before the signboard is in a flaming condition. At that time it is not of much importance whether the signboard is inflammable or the reverse. The painters say there would be no objection raised by them if the size of boards were restricted, so that windows need not be blocked, and they would co-operate in carrying out stringently all regulations to insure the safety of the public. That signboards are too obtrusive in London is undeniable, and it would aid architectural effect if more modest dimensions were demanded. The risk of danger would be diminished by that sort of arrangement. As long as wood is employed there is, however, a chance to obtain some variety in lettering; but if fire-resisting materials are used, there will be sameness in the signs, and when houses are not uniform that would not always be an advantage.

ADELPHI BANK, LIVERPOOL.—THE BRONZE DOORS.

BATHS AND LIBRARY, GREAT SMITH STREET, WESTMINSTER.

REREDOS, PONTARDAWE.

THIS reredos is now being erected to the memory of the late vicar, the Rev. DAVID JONES, and also the late curate, Rev. T. E. DAVIES. The centre canopy of the reredos is richly cusped and moulded, and terminates with a carved stone cross. On each side of the canopy are two niches, with the figures of St. PETER and St. JOHN. The centre portion is filled in with gold mosaic, and the Agnus Dei above in green and white mosaic. The arches on each side are supported with Numidian marble columns, with Irish green marble slabs at back. The stone is Caen. The whole of the work is being carried out from the designs of Messrs. WILSON & MOXHAM, architects, Swansea.

FINDLATER CHURCH, DUBLIN.

ARCHITECTURE AND ITS CIVIC AND COMMERCIAL VALUE.*

SOME time ago a client asked me if I would explain one thing as to which he was in doubt. It was, When was a building merely building, and when was it entitled to be considered architecture? I explained as well as I could in the limited time at my disposal. The reason I mention the incident is because it led me to think, if he wanted information, may not many others? I tried to remember if any lecturers had dealt with the subject; I could not think of any. It is such a pleasure to a lecturer to find a portion of a subject that is new that I determined to try what I could do with it. I could, of course, give definitions easily enough, but how could I by diagrams bring home practically the distinction to non-professional minds? I prepared some diagrams and used them at the opening lecture at King's College. Since then I have made more, and I trust sufficient to fully illustrate this part of our subject.

I propose (1) to show you how architecture can be reduced to mere building. (2) Then, reversing the process, to show you a drawing of mere building, and then drawings showing how such building may be treated so as to make it partake of architecture. (3) Next I will give you an illustration as to the treatment of the simplest form of building—the cottage—and how some character may be given to it. Afterwards I propose to ask you to consider with me one essential element, without which there can be no good architecture, namely, proportion; and then we shall take a rapid survey of the characteristics that distinguish the architecture of the different nations.

As I trust we shall all then understand what architecture is, we will deal with (1) its civic, and (2) its commercial value.

Probably the best, the clearest definition is one I have given on a former occasion:—"Architecture has a definite object over and above that of giving pleasure. She has to serve the needs of man, and is therefore a useful art as well as a fine art. Architecture, therefore, recognises utility as the basis of her work, on which she erects a superstructure of her own with grace of proportion and beauty of ornament. Without such additions, utility alone would give us, not architecture, but only building."

Some think that architecture means elaborate decorations, carving and ornament. Even that well-known author, Mr. Fergusson, in his analysis of architecture, appears to lay too much stress on ornamentation when he says:—"Architecture is nothing more or less than the art of ornamental and ornamented construction."

It recalls to my mind a building, the ground floor of which was Grecian, the first floor Roman, the second floor Italian, and the roof and turret Gothic—all built without the slightest regard one for the other. It was certainly ornamented construction, but one does not wish to see such another example. No, bear in mind that mere ornamental building cannot satisfy the taste. There must be proportion, without which no building can please, and this is the next division of the first part of my subject.

All-important in architecture is proportion. As I have said, I can hardly lay too much stress on this requirement. You may ask, Are there no rules to help us? Did not the architects of antiquity and the Mediæval ages have any to guide them in obtaining the glorious proportions we see in their buildings? No doubt they had rules, but as we have no record we can

only by measurements of the building endeavour to find out what they were. For example, three different systems have been given to the Egyptian pyramids:—(1) the triangle; (2) the astronomical; (3) the ten horizontal to nine vertical.

No matter how the proportion is arrived at, we shall not be wrong in drawing the conclusions: (1) A building without proportion is utterly, hopelessly bad. (2) A building, no matter how simple, if in proportion, is good and pleasing. (3) A building in good proportion and with ornamented construction is to be desired, and will give much pleasure. As, therefore, no amount of ornament or even ornamented construction is of any avail in producing a pleasing effect without proportion, proportion is the very life-blood of architecture. To test whether designs would look well in execution, it has been suggested to wash the perspectives all over with a dark tint of Indian ink, so that only the outline would be left (like, in fact, as it would be seen in a London fog), the opinion being that if the design then looked well, it was certain to be a success.

I have not time to speak of the addition to proportion of beauty. You can easily imagine how such addition produces perfection in architecture.

I next have to explain the leading characteristics of the different styles. The original dwellings of man, as you no doubt know, are divided into three classes by Gwilt:—1. The cave, for the hunter and fisher. 2. The tent, so often mentioned in the Bible, for the shepherd. 3. The hut, for the agriculturist.

I will only give you a few drawings of the cave. One called the Tiger Cave is very remarkable, although not so extensive as the cave at Karli, which is on the road between Bombay and Poonah (formed 100 B.C.). The latter is 126 feet in depth, 45 feet 7 inches in width, and 45 feet high in the centre, with fifteen pillars on each side, dividing it into nave and aisles, and it has also a circular apse. The Tiger Cave is curious, because its extended jaws form a verandah leading to a small compartment within.

I may mention that nearly all the cave excavations in Egypt are tombs (I show you many illustrations placed on the walls). In India they are formed as dwellings, temples and monasteries. In Asia Minor the caves are in many examples decorated with a façade of the Ionic or other types.

Let us pass to Egypt. The Egyptians, I should mention, were pre-eminently a building race, and our knowledge of their entire history is due to the records they have left in and on stone. Their pyramids were erected 3,000 to 3,500 years B.C. It has been well said, the monuments of Egypt give life and reality to their whole history. It is impossible for any educated man capable of judging of the value of evidence to wander among the pyramids and tombs of Memphis, the temples of Thebes, or the vast structures erected by the Ptolemys and Cæsars, and not to feel that he has before him a chapter of history more authentic than we possess of any nation at all approaching it in antiquity, and a picture of men and manners more vivid and more ample than remain to us of any other people who have passed away.

Again, you cannot examine the interior of the Great Pyramid without being struck with astonishment at the wonderful mechanical skill displayed in its construction. The immense blocks of granite, brought a distance of 500 miles, are polished like glass, and so fitted that the joints can hardly be detected. The leading characteristic is enormous solidity of construction. It may well be said they built for eternity. In proof, look at the photo. of the building at Karnac, which is considered the finest. Fergusson says:—"All combine to stamp this as the greatest of man's architectural works; the twelve central columns which rise to the top of the clerestory are so large that 100 men could stand on each cap without crowding."

Next in antiquity is the Assyrian style, which dates from 1341 B.C. to 332 B.C. The form of building is of the heavy massive type, relieved with glazed tiles and bricks—I give two examples, Nineveh and a fishing pavilion, taken from the sculpture at Khorsabad. These exhibit all the parts of an Assyrian order with its entablature. The period is more than 1,000 years later than the Pyramids. I show one illustration of the difference in stability between the Assyrian and the Egyptian. It is that of the walls of Babylon, which were 390 feet high and 90 feet thick; there is now practically nothing left.

The great charm in Grecian architecture is the refinement of line, as exemplified in the Parthenon erected at Athens about 400 years B.C. It is considered that Grecian architecture, in this building, reached its highest perfection and beauty. In sculpture, also, we find a great advance; the conventional figure of the Egyptian and Assyrian period is gone and we have work unrivalled in any country and in any age.

Pause a moment to think that some 2,000 years ago perfection was attained; at least, the work is still the admiration of the world. And it adds to our wonder if we recollect that all these glorious works were accomplished in the short space of 150 years.

The language of Mr. Fergusson, in speaking of the Par-

* A lecture by Professor Banister Fletcher, delivered at the National Building Exhibition.

thenon, may seem excessive praise, yet we may venture to agree with him :—

"It is undoubtedly the most beautiful building in the world. It is true it has neither the dimensions nor the wondrous expression of power and eternity inherent in Egyptian temples, nor has it the variety or poetry of the Gothic cathedral; but for intellectual beauty, for perfection of proportion, for beauty of detail and for exquisite perception of the highest and most recondite principles of art ever applied to architecture, it stands utterly and entirely alone and unrivalled, the glory of Greece and a reproach to the rest of the world."

We pass now to a very different character of art. Roman architecture was not matured, like the Grecian, in peace, but in war and conquest. Rome, you will remember, from the possession of the Seven Hills, gradually carried her sway at the edge of the sword over all Italy and the entire then known world, seeking only, it has been said truly, the acquisition of wealth and power. Then, and not till then, she became the centre of all the arts and of all the sciences, and more numerous and larger buildings were set up in Rome, and her dependent cities, than have ever since been erected. The architecture displayed greatness in the mass, grandeur in the conception, and an expression of power, whilst it lost the refinement and grace of the Grecian.

The next style is the Romanesque, a modification of the Roman forms, in order to adapt them to Christian purposes. In Italy and south of France this style continued to be practised till the sixth or seventh century.

In Western Europe architecture on the dissolution of the Roman Empire seems lost for a time. And history next brings us to the same Romanesque architecture which was used by the Western barbarians, who overthrew the Roman Empire. In England we know the Romanesque style by the name of Norman.

I have now indicated to you how the styles of architecture arose from the early caves, tent and hut, and in so doing have dealt all too briefly with so much of the history of the world as is written in stone.

Time will not permit us to deal with the development of the Gothic, except to mention that the progress of Gothic in England after the Norman is called, first, Pointed or Early English, next Decorated, and last, Perpendicular. The period of this last style is the fifteenth and sixteenth centuries. Nor may I stay to treat of the glories of our Gothic churches and cathedrals. I can only remind you of the words of Madame de Staël. Speaking of them she says:—"A cathedral is a glorious specimen of thought in stone, whose very windows are transparent walls of gorgeous hues."

With regard to Saracenic, Etruscan, Renaissance, Indian and Chinese, all I can do is to invite you to look at examples.

I have already mentioned the subject of application. I have long thought that a lack of idealism is the great defect of the present day. We work, and rightly too, for material improvement, betterment of social conditions, &c., but surely at the same time we ought to work for something else. Might not that something else be to endeavour to make the city we live in the most pleasing, aye, even the most beautiful, in the world? And this brings me to the next division of the subject, to the value of civic architecture.

You to whom I am speaking must in time be among those who govern the policy that can help forward or mar this ideal. Try, then, to get rid of the too common conditions of building. Most people say, "I want a certain quantity of space covered in and certain showy ornament, and it must all be done at such a sum." Do you imagine that that was the way they built the glorious buildings the mere illustrations of which have, I hope, given us so much pleasure to-night?

As I propose only dealing with what civic authorities can do, I must eliminate all works of architecture which possess value from age. As, for example :—(1) The glorious pyramids and architecture of Egypt; (2) the old temples and architecture of Greece and Rome; (3) the beautiful cathedrals of the Middle Ages. Also those which possess value from old association, such as Shakespeare's House at Stratford-on-Avon and Holyrood Palace, because their value is due to events that cannot be created by civic authority. I do so because my object is to show you to-night that architectural outlay may be profitable, that municipal and other authorities may do worse with the money at their command than spend it in the architectural adornment of their cities and towns; and clearly it is necessary to omit from our consideration buildings they cannot now create.

Well, let me give my illustration. Formerly Paris attracted visitors by its beautiful thoroughfares and buildings. London at that time was only a place of business, which all left who could. I will not dwell on what London was, as it is not a pleasant subject; but rather, by mentioning the improvements, leave the imagination free to reflect what it must have been before.

We have, amongst other improvements :—The Embankments (Victoria and Albert); Northumberland Avenue; Hyde

Park Corner; new widened thoroughfares around Belgravia, on the Duke of Westminster's estate; Victoria Street; Queen Victoria Street, and widening of the Poultry; Commercial Street and Great Eastern Street; the streets through the rookeries of Seven Dials; the railway extensions and monster hotels; the new clubs; new Natural History Museum; the new theatres; the Imperial Institute; the new shops and stores, the improved residences, and other buildings, all these have entirely transformed London, and the result is that London, which formerly was as I might have described, but have left to your memories, is now preferred by very many to Paris as a residence—a sure proof that architecture has civic value. For the moment put aside the metallic element, and let us see what other civic value the citizen gains :—1. The enjoyment of the beautiful. 2. The use of the widened and ennobled thoroughfares. 3. Imperceptibly the spirits are lighter and life brighter where the surroundings are improved. It is curious, by-the-by, that the first visit of royalty to a foreign state was not alone to see the greatest king who, we are told, has ever lived, for if you refer to that book you know so well, it says the Queen of Sheba went to see King Solomon and the house that he had built. The house divides with the king the object of that visit. 4. The citizen has his delight in showing his town to visitors from afar, and also has the pleasure of proper pride in so doing, and the profit from increased custom. That my opinion is not unsupported, I quote Sir Samuel Fergusson as to the value of architecture. "Architecture is delightful in itself, and valuable to society," and he properly adds, "in proportion to its power of exalting the soul and refining the intellect."

To convince you that it rests much with you, let me remind you of the words of a good authority :—"If we are still to have great poets, great painters, great sculptors, great architects, and great musicians, the people must have aspirations as noble, a taste as refined, as those of the ages in which these arts flourished." To show you that this is not a solitary opinion, I quote what my friend, Mr. Alfred Gilbert, R.A., has said :—"The stumbling-block to the English was the practical; everything that did not present the idea of immediate advantage seemed to be impractical. Till the love of beauty was once more alive among them, there could be little hope for art." Why do I press on this necessity of self-education? Because we can never hope to have London made beautiful without it. How can we expect taste or beauty to be considered by the "powers that be" until there is an earnest desire for it by the people? In fact, I doubt if they are not right to neglect it. They are your representatives, and really they do represent you in your present mood.

Will one quotation from Ouida, that clever writer, stimulate you? It is :—"When the beauty and wealth of a great society are displayed in its architecture, in its gardens, in its public pageantries and festivals, then the body of the public is a sharer in and gainer by them." We must now claim rights of beauty.

Let me illustrate this. Formerly a man claimed—and his claim was admitted—to do what he liked, with his land. Gradually it was found so intolerable to the general community that laws were passed restraining him from doing anything thereon that could be a nuisance. The most modern probably of such restrictions is as to line of frontage, that he shall not in building come in front of other houses. Now we want to go a little further, I fancy, and say when in building you are depriving us of light and air, and oftentimes of trees and landscape, we, the passers-by and neighbours, are entitled to demand (while we agree you are entitled to so injure us) that you shall not also injure our eyes by building an ugly building, because it is unnecessary injury. We are entitled at least to have a pleasing building.

It rests with the people whether or not there shall be civic improvement. In proof I quote from the *Scottish Art Review* :—"What vast sums have been expended on public buildings without an adequate result. All this is owing to the indifference of the public."

The public has first to be imbued with a love of architecture to recognise its responsibilities. You may wish to know what ancient nation best affords you a model, not to copy, but to suggest. I answer, the Roman. The municipal architecture of the Romans consisted of the basilicas, the theatres, the baths; the Roman temples had neither the size nor the grandeur of other public buildings. The people cared most for government and justice. As one example of the size of their public halls of justice I take Trajan's Basilica, 100 feet wide, 360 feet long. Take another public building, the Flavian Amphitheatre, generally known as the Coliseum, commenced by Vespasian, completed by Titus, his son—627 feet long, 520 feet wide, 166 feet height of outer walls; $5\frac{1}{4}$ acres of land; which seated 50,000 spectators.

Next in splendour come the Roman baths (or *thermæ*). I will not trouble you with the names of the many erected; one, the Bath of Caracalla, a square of 1,150 feet each way, contained lecture-room, gymnasia, &c. Yet reflect, while ancient Rome could have such grand municipal buildings, the City of

London—the richest, the greatest city—has not one bath. I proposed a resolution at the recent wardmote and it was unanimously passed that the City should be asked to build proper swimming and other baths, and I trust we may hereafter have them. Other Roman civic adornments were triumphal arches, tombs and memorials, bridges, aqueducts, palaces; that of the Cæsars on the Palatine Hill at Rome covered about $5\frac{1}{4}$ acres, 1,500 feet by 1,300 feet. The money spent must have been enormous.

Surely if Rome could have such grand buildings we may also. It is not only, however, buildings we need; I would ask you to attend to the thoroughfares, to open spaces, to covered spaces, and, had I time, I should like to point out how much improvement to the health and comfort of this city might be effected in respect of the courts and alleys without great expenditure—in fact by an expenditure that would be profitable to the County Council—but I must reserve this for some other opportunity.

May I point out to you before passing to the last part of the subject that, whilst doing your duty to the community in educating yourselves to be able to take your place in its councils, you are by studying art and architecture adding to your own power of enjoyment? 1. In your holidays you will have an additional source of delight. 2. The delight is constant—unlike science—because the principles are eternal. Once learnt, learnt for all time. 3. You can always have the pleasure, and without payment, of enjoying the exteriors of the buildings.

We come to the last part of my subject, the commercial value, certainly the lowest ground on which I can advocate architecture, and yet I fear it is the one most likely to command attention in this age, which is always asking, Will it pay? Let me endeavour to prove this by a very old example. Belgravia was formerly called the Five Fields; the land was thought of little value, lying so low and so near the river as to be thought marshy. Well, how did Cubitt deal with it? By building small houses, as many would have done, considering such houses best adapted to so unpromising a site? No, he adopted quite a different treatment of the place. By putting thereon palatial residences—I am speaking of what was considered palatial at that time—and thus made land of comparatively little value of great value.

Let me give you more recent instances—Hankey's residences, ugly though they be—and another still more recent illustration, Westminster Town Hall and the residence-flats near it, which were built in almost the lowest slum of London. By the expenditure of large sums of money in architectural work the ground value of the land has been raised enormously.

I have so much exceeded my time I fear to multiply instances, or I could, by referring to many towns in England, show how intense has been the increase of value in land by erecting on it architectural buildings which, to the unthinking, may have appeared a waste of money. In reality, such outlay has been the most profitable outlay possible.

I would only detain you further a few moments, while I touch upon the commercial aspect as it affects tradesmen. Often have I heard them say the outlay in rebuilding or improving architecturally has been most profitable, and I feel confident the tradesman who so spends money—of course, I assume judiciously—has not only the advantage of passing the necessarily larger part of his existence in pleasanter premises, but has increased trade. I remember one client said, "I don't mind what you spend"—he is rapidly acquiring a fortune.

It is a charming thought that one of the nation of shopkeepers (as we have been called) can beautify his native town with profit to himself, with pleasure (for to be the occupier of an architectural building must give it), and with the serene delight that he is increasing the attractiveness of his city or town.

Let me sum up briefly. I have tried (1) to explain what is and what is not architecture; (2) to explain that architecture has civic value enduring through all time; (3) that commercially architecture will pay. I trust that I have succeeded. May I, in conclusion, impress on you the value of architecture itself. I quote from Longfellow:—

Ah! to build, to build,
That is the noblest art of all the arts;
Painting and sculpture are but images,
Are merely shadows cast by outward things
On stone or canvas, having in themselves
No separate existence. Architecture
Existing in itself, and not in seeming
A something it is not, surpassing them
As substance shadow.

The Students of the Battersea Polytechnic Institute and the Bromley (Kent) Plumbing Class will visit the Highgate Museum of Sanitary Appliances, under the direction of Mr. S. C. G. Fairchild, to-morrow, Saturday, the 14th inst., at 4 P.M.

THE ASSESSOR IN AMERICA.*

THERE is no subject which more properly comes before an association of architects than that of competitions. When we are engaged each for our own clients, we are not much concerned about the manner in which other offices are run. We may derive mutual help from association with each other, but the work of each architect is built in plain sight, and we can all see what he is about without asking his leave, and the professional journals give more in the way of practical information than we are likely to imbibe at a meeting such as this. When, however, it comes to butting our heads together for the amusement of the building public, it becomes a fair question whether the illusive prospects of a prize fully repay us for our sore heads.

If we must engage in contests of strength, it is important to have some rules for the game to secure fair play, and it is most essential that the referee be competent and impartial. We usually engage in these architectural combats for the gratification of a committee who form the audience, and the prize is awarded by a vote of the spectators.

It has been the opinion of learned conventions of our profession that the average committee is not competent to decide contests of so technical a nature; and, therefore, we have made a vigorous effort to secure the decision of architectural competitions by "experts." It ought, therefore, to be a matter of interest to examine into the workings of an expert decision in the case of a competition in which a number of members of this Association engaged.

The city of Milwaukee proposed to erect a building to accommodate the public library and the public museum. This building was to occupy a prominent location, and cost half a million dollars. Architects were invited to present competition sketches in accordance with a programme in many ways attractive. The drawings were all to be a uniform scale, and perspectives in outline only. The programme was carefully prepared. The successful architect was guaranteed 5 per cent., and in addition four prizes of 500 dols. each were offered for the designs next in merit. This invitation attracted 74 designs, and the first item of interest is to note where the designs came from. There were 14 from Milwaukee; 17 from Chicago and vicinity; 5 from Michigan and Ohio; 21 from the eastern States, ranging from Boston to Baltimore and Washington; 2 from the South; 6 from St. Louis and Kansas City; 7 from Minnesota; 1 from Colorado; and 1 from Canada. There were 26 from east of Milwaukee and Chicago, and 15 from west of these places. It is interesting to note next that these designs must have cost on an average 500 dols. apiece (many cost more than twice that sum), or a total of 37,000 dols. for sketches, while the total amount to be paid for architectural services, including prizes, is only 27,000 dols.

These designs, after they were received, were displayed for some days to the public. Many of the competing architects visited Milwaukee to see how their designs compared with their competitors. This led to friendly meetings among the competitors, who examined each other's designs and commented upon their excellences. Each architect was naturally anxious to determine who were his most formidable rivals, and therefore scrutinised the various plans with this object in view. There was a general agreement among those who saw the plans, both architects and others, that the designs might be divided into three groups. First, a few designs in which the problem had been solved in a fairly satisfactory manner, any one of which if built would give both the library and the museum the accommodation desired, and be at the same time a creditable architectural monument adapted to its situation. In the second class were a few more designs, evidently by competent architects, but which did not solve the problem. The exterior might have handsome features, but it did not fit the location. The plans might show some fine rooms, but they were not arranged as called for in the programme, and would not answer the purpose of the library and museum. Then came the third class, much the largest, of designs which, from a wild exterior or a still more untamed arrangement of plan, were so wide of the mark as to be unworthy of serious consideration.

When a number of architects work on the same problem, it is to be expected that, other things being equal, those who give the most study to the problem and have the best opportunities for getting information will produce the best designs. Those who are in the neighbourhood, naturally feel the greatest interest, and are likely to give the subject the most attention; they also have the best opportunities for understanding the problem in all its bearings. For those reasons Chicago architects feared principally the competition of Milwaukee, and the Milwaukee architects feared most their Chicago competitors. When the plans were made public it was the general opinion that there were at least two plans by Milwaukee architects that would rank among the first five. These were by H. C. Koch & Co.

* A paper read by Mr. N. S. Patton before the Illinois Chapter the American Institute of Architects.

and Ferry & Clas. These firms had undoubtedly had the problem under consideration for a longer time than their more distant rivals. In contrast with these it appeared that, apparently without exception, every plan from a more distant point than Chicago had some serious defect arising from a careless or insufficient study of the programme, which should be sufficient to disqualify it for the highest rank.

After the public exhibition of the plans, the next move of the library and museum trustees was to engage the services of Professor William R. Ware, of the School of Architecture of Columbia College, New York, as an expert to select the prize designs. As far as we know this was acceptable to the competitors. Professor Ware spent somewhat less than four days in Milwaukee in examining the plans, and then returned to New York, from which place he sent the report. When the names of the prize-winners were announced, there was with all who had examined the plans surprise amounting to amazement. The two Milwaukee designs were safe, but those who had been counted their strongest rivals were nowhere. Every one awaited with great interest the publication of the expert's report to know on what principle of selection the choice could have been made. This report from a professor of architecture, laying down the correct principles of design, should be of great value to the young men of the profession, many of whom tried their luck in this contest. It is this report that I propose to consider in the hope of extracting some suggestions for the aspirants to honour in future competitions. The report begins:—

I have examined the seventy-four designs submitted in competition for the Milwaukee Public Library and Museum, and have carefully studied those among them, about twenty-five in number, which seemed to be of promise. Of these the five numbered 17, 50, 51, 53 and 74 seem to be, on the whole, the most acceptable, though none of these offer as they stand a perfectly satisfactory solution of the problem. Any of them, however, would, if subjected to certain obvious modifications, perfectly well answer the needs of the city and provide a handsome and convenient building.

The necessity of thus changing the designs, in order to adapt them to the requirements of the case, arises in the main not from lack of skill and judgment on the part of competitors, so much as from their having mistaken the meaning of some portions of the paper of instructions, as in the case of the museum, or attached undue importance to the requirements which it now proves to have been impossible strictly to follow without sacrificing other things more important, as in the case of the lecture-room. This does not affect the merit of a design as a solution of the problem presented, though it may make it unsuitable without alteration. This is especially the case in regard to the museum, which some of the competitors have supposed to be intended for pictures and statuary, and for miscellaneous works of art, when in fact it is in the main a museum of natural history.

Suggestion first. It is no detriment to a competitor if he misunderstands the programme. If an architect is called upon to plan a museum and he submits designs for an art gallery instead, he is perfectly excusable. He may not know the difference. The report continues:—

The scheme best suited to such a museum seems to be a series of large rooms, occupying one over the other the whole of the wing assigned for this purpose, with no entrance from the side street. But as this was not especially stated in the instructions, and as it was impossible for the competitors to have known this, especially for those living at a distance, it would be unjust to reject the designs that embody a different idea, simply because it happens to be a mistaken one.

If it was impossible for the competitors to have known this, or to learn it in four weeks, how did the Professor find it out in four days? It would appear from this and other statements in the expert's report, that he has never read the "instructions" to which he refers, for these describe the rooms for the museum as follows. After mentioning various special rooms it says:—"The remainder of the first storey should be arranged for exhibition purposes. Second storey: This storey shall contain one large hall. Third storey: This storey shall be the same as the second, and contain a gallery." There is no side entrance called for, although every premiated design has this undesirable feature. Thus the printed instructions call for just what the Professor says "it was impossible for the competitors to have known." Notice that those "living at a distance" must be cared for tenderly. Before engaging in a competition it would be wise to move to a distance; your mistakes will then be overlooked. The report continues:—

Moreover, it would not only be unjust to the competitors, it would be contrary to the interests of the city, which it is the first duty of the committee to protect. To deprive the city of a design in other respects admirable because in certain particulars, which can easily be altered, it requires alteration, would be contrary to public policy.

This is worth knowing; the first duty of a committee on a competition is not to give an unbiased decision between the competitors, but is to protect the interests of the city. Granted, but the expert was employed to select the designs that best fulfilled the demands of the instructions. Why did he not address himself to this task and leave the protection of the interests of the city to the committee?

Now, this particular alteration can easily be made in the plans which are herewith presented that do not already show this arrange-

ment. This being so, the question, Which design best accommodates the museum? ceases to be an important consideration in choosing among them. All can be made to furnish just the accommodation that is most preferred.

With what a masterly stroke of logic does our expert prove that with a museum the interior arrangement is of no consequence in judging between plans. The writer knows of at least one competition for a museum in which the architects thought it necessary to spend much study on the arrangement of the interior, and even visited distant cities to learn the best museum arrangement. The plan adopted was largely on account of its superior adaptation to museum uses, but then the committee were not "experts."

What has been said of the museum applies, though with less exactness, to the library. The trustees of the library know just what they want, but it was impossible for the competitors to know it with exactness. They had to work, for the most part, very much in the dark.

How did the Professor find out that "the trustees of the library know just what they want"? It is a rare thing for trustees to know what they want, but in this case they did know and told the competitors very plainly in the printed instructions what they wanted. Some trustees have learned that it is one thing to know what they want, and another thing to get it when an architect stands between them and this desirable object.

The Professor says the architects had to work for the most part in the dark. No one had to work in the dark unless he was too lazy to turn on the light. The instructions were unusually explicit. We are calmly informed that "some have shown great skill, but have avoided just what is, in fact, the desirable thing." In what does skill consist if not in doing the desirable thing? But the Professor adds "insult to injury" by remarking, "Others have by hit or by wit done almost exactly what was wanted," the insinuation being evident that it was probably not by wit. The plain meaning of the above extracts is that in the mind of the expert the arrangement of a good plan is a matter of accident, and he proposes to award the prizes, not in accordance with the results before him, but on his estimate of the skill of the designers, as shown by their avoiding what is desirable. It would seem that the man of great ability who is too lazy to read the programme with care should suffer if he miss the mark; while the one, whoever he may be, who by "hit or wit," or more likely by skill, experience and hard work, does "almost exactly what is wanted," should have the prize. Indeed, the Professor has some twinges of conscience on this point, for he adds by way of apology:—

It is right that these again should have a distinct preference, and should not be set aside except for some paramount excellence, which other designs exhibit and they do not. This claim for consideration is stronger in the case of a good library plan than in the case of a good museum plan, the library problem being a more complicated and difficult one, and the prospect of satisfactorily altering an unsatisfactory scheme being much less promising.

Next in the report is a reference to the lecture-hall, which made trouble for nearly all the designers because it was stipulated to be on the first floor where it interfered with other more important rooms. The Professor's remarks on this point are eminently fair toward all the competitors. The report then turns to the question of the design:—

But the most important element in a design is its architectural character, and this element is not susceptible of such manipulation. In this respect the different designs must be judged as they stand. The architectural treatment without and within is not open to such modification as substitution. It is something individual and personal to the design and its author. The taste, skill, knowledge and judgment evinced by any one of these competitors cannot be transferred to another. In choosing among the designs submitted, this is, accordingly, a consideration of paramount importance. The object of a competition, indeed, is not only to secure a convenient and suitable building, but to secure evidence of the taste and skill of its designer. The exhibition of taste and skill, and of professional capacity and resource is, accordingly, a main consideration in choosing among the designs submitted. This cannot, of course, be transferred from one set of drawings to another. In a building like this, which is eminently a public monument, this consideration is of exceptional importance. This does not mean that there is no substantial ground of choice between these designs. It means that artistic considerations should, in such a building, have a certain precedence, since matters of practical convenience can always be secured with sufficient care and pains, while all the care and pains in the world will not change personal and professional qualities.

Here are several novel propositions which rest on no more substantial foundation than the mere statement of their author. In the first place, is the assertion that while the plan of a building can be radically modified, no such changes can be made in the design, a statement that is disproved by the experience of every architect, for is it not a common practice to prepare a plan and submit two or more designs of widely varying character for the exterior? Professor Ware is evidently of

the opinion that it is a more difficult task to make a good exterior than a good plan. The falsity of this opinion is proved by this very competition, in which there were without question fewer good plans than good designs. The student of architecture learns the elements of design first; he only learns how to make a practical plan after years of experience. If the statement that "the taste, skill, knowledge and judgment evinced by any of these competitors cannot be transferred to another" holds true in the matter of the design, as the Professor informs us, much less can they be transferred in the matters pertaining to good planning.

Suggestions for exterior design are much more accessible to architects than are interior arrangements. As will be illustrated later, it is often possible to draw inspiration for a façade from some European structure, but more difficult to find any plan that will fit the new conditions. The genius for good planning is as rare as that for good designing, but what is still more rare is the ability to unite a good plan and a good design, so that the design shall express the plan. This element of design, that it shall be a grammatical expression of the main features of the plan, is entirely overlooked by the Professor, probably because the designs selected by him are so lacking in this respect. They are masks that hide instead of expressing what is behind them.

The first plan mentioned, by Nettleton & Kahn, has end pavilions, but no centre pavilion, which might indicate the double nature of the building—library and museum, but an examination of the plan reveals the fact that there are no walls separating the pavilions from the central portion, the reference reading-room being half in the pavilion and half out of it. Thus the divisions of the façade do not express the arrangement of the interior. The Professor remarks about this plan:—

As to the library, while the arrangement of the delivery-room and the book-stack could remain substantially as shown, the position of the reference-room and service rooms would probably have to be reversed. It would hardly be worth while to contemplate so much alteration if it were not for the admirable character of this design, both within and without.

The "so much alteration" means nothing less than a new plan for one-half the building. The location of the reference-room in relation to the book-stack was one of the most important, and at the same time most difficult, problems of the design. A failure in this respect is radical, and is not one of the minor points that can be overlooked. The report criticises the narrow main entrance, but overlooks the still narrower communication with the book-stacks, which is entirely inadequate.

The next two designs, by H. C. Koch & Co. and Ferry & Clas, were by general consent placed among the best, and it was no surprise when they were so placed by the expert. The faults of planning are not radical, but the character of the elevation of the Ferry & Clas design is a curious commentary on the Professor's remarks about the architectural treatment being something individual and personal to the designer. He says:—"The elevation is to my mind one of the best, if not the very best, of them all—elegant and sufficiently dignified, and a great improvement upon the library at Leipzig, which it notably resembles. The central feature is much more to be commended." This small cut of the Leipzig library is sufficient to show that the Ferry & Clas design is almost a facsimile of it, the only essential modification being the addition of a dome to the centre. A comparison with the agricultural building of the World's Fair shows where design for this dome was found. This free-and-easy manner of obtaining designs is, according to Professor Ware, something individual and personal. Other members of the profession may well congratulate themselves that such architectural kleptomania is not a contagious disease; and, therefore, they need not fear that they will wake up some morning and discover that they have unconsciously assimilated another man's design by swallowing it whole. Undoubtedly Professor Ware will claim that such a combination of two designs with the modifications made is allowable in architectural practice, and is a proper method of producing a design. If we grant this argument, what ground is left for the claim that no other architect could have adapted the design of the Leipzig library to the plan of the Milwaukee building? The plans submitted by Ferry & Clas show much greater evidence of originality and skill than the elevations, and no doubt required the expenditure of more study. This method of making a design by borrowing it ready made from another building has the unavoidable result that it does not fit the interior; this is shown in a striking manner by the second-storey plan, in which the museum is cut off from the front by two small rooms. The only rational treatment of a design in which each storey of the museum is one large hall, occupying the whole of one wing of the building, is to bring this hall to the front and recognise it as a feature of the façade. Not one of the premiated designs adopts this treatment; either the museum is not brought to the front at all or it is not indicated on the façade. One would suppose that a professor of architecture would be thrown into a nervous paroxysm by such a plan as that of the second storey

of the Ferry & Clas design, in which the museum stops at one mullion of a triple window, but he passes it without a comment. The next design, by Andrews, Jacques & Rantoul, is described as exhibiting almost more than any other the qualities of an elegant and scholarly arrangement that should characterise a building of this class. He says:—"The reference-room is ingeniously placed, one half storey above the main floor, and the newspaper-room one half storey below." This is one of the instances referred to in the report in which great skill has been shown in doing what was not wanted; but the Professor immediately apologises by saying, "but this is not essential to the design and need not be seriously considered." Thus it was meant as a joke that the reference-room was placed one-half storey higher than the main floor, when the programme explicitly states that the convenience of bringing books from the stack to this reference-room is an important consideration. When the attendants run up and down the stairs to the reference-room they will be reminded perpetually of this remarkable witticism of the architects'. The space marked "delivery-room" is in fact a public corridor, being the only means of access from the interior to the librarian's office, cataloguing-room, general reference-room and newspaper reading-room. The book-stack is so arranged that some of the cases are without direct light and there is only a single very narrow entrance; but according to Professor Ware the interior is of little consequence, and we turn our attention to the exterior of this design. To our great surprise we find the Professor remarks that "the external aspect does not quite bear out the promise of the interior; but it is simple and dignified, and if treated with the elegance of detail that the handling of the problem seems to promise will be handsome and satisfactory." That is to say, if money is lavished on the detail, our attention may be distracted from the ungainly aspect of the building as a whole. If this design with its flat-topped part placed against the end of the main building is suitable and satisfactory, then all the other designs which show a symmetrical façade extending from street to street must be mistakes.

As the Professor remarks, the interior of the reference-room is not to be taken seriously, so the exterior must be meant as a joke. The architects in their own description of the plans state that this wing is given a separate treatment for the sake of "symmetry." The last of the premiated designs is that of Boring & Tilton. The Professor has found very little to say in favour of this plan; and although he makes some criticisms, he has failed to notice that the book-room is too wide to be lighted in the centre.

This paper is not intended as a criticism of the premiated designs, but is a criticism of the principles laid down by Professor Ware in making up his decision. It is impossible to give a just criticism of the design when only one floor plan has been published; but this would not have troubled our expert, for only once does he even refer to the existence of more than one floor in the library portion, and then makes no comment upon it. The report is very superficial; in fact the Professor might better have announced the prize designs without any report, for he makes no comparison between them and the others. Perhaps he had in mind the anecdote of the old judge who advised the young one never to give any reason for his decision, otherwise he would certainly get himself into trouble. A proper report would at least have taken account of the twenty-five designs that he states were worthy of serious consideration, and have instituted comparisons between them to show in what particulars those selected were superior. One is forced to the conclusion that this was not done because the examination of the plans was so superficial that the expert was unable to make a comparison. The report gives throughout evidence of hasty and incomplete examination. There were several intricate and difficult problems to be solved, especially in connection with the library. The arrangement of the stack-room to give maximum floor area with the best lighting required much study on the part of the designer. No reference is made to the stack-room in the criticism of any design except that of Ferry & Clas, where it stated that the form of the book-stack "is especially ingenious"; but we are not told in what this ingenuity consists, or whether there is any benefit arising from such ingenuity. No reference is made to the lighting or to the provision for heating and ventilation, and finally the limit of cost is ignored altogether in the awarding of prizes. The expert forgot about protecting the interests of the city. The report says "the final choice of the committee must probably be determined in large part by consideration of expense." It is a valuable point to remember in future competitions in which an expert is to be employed, that although the question of expense may be considered in choosing between the prize designs, it will not count in awarding the prizes. Under these conditions most architects will work to secure a prize, and then take their chance with the committee. In this competition many architects, recognising the fact that the limit of cost was low for a building of such a size, conscientiously made their designs simple in character, avoiding such features as domes,

The case has brought expert decisions in architectural competitions into as ill repute as expert medical testimony in insanitary cases. The courts are wiser than to decide on the evidence of any one so-called expert. The first lesson we can learn from this case is that we should not risk the decision of an important competition to the whim of any one man. It is difficult to draw further lessons unless we know whether the decision of this competition is exceptional in its character, or whether it is the best we may expect from an "expert."

In the first case we can only agree with the architect who remarked that it appeared as if the Professor had done a cheap job in Milwaukee. If the second supposition be correct, then we may well doubt the qualification of a professor of architecture to decide a competition more serious than that between students.

AMERICAN ARCHITECTS AND PUBLIC BUILDINGS.

IT was believed by American architects that the Tarsney Act, which was lately passed, would be loyally enforced by the Government, and that the designs for public buildings were henceforth to be obtained by competition. About a year ago representatives of the American Institute of Architects entered into correspondence with Mr. Secretary Carlisle on the subject, and were assured that arrangements for the purpose were in progress. In last November Mr. O'Rourke, the supervising architect, in reply to a letter, wrote:—"I have no reason to believe that there is, or has been, any reason for deferring action in this matter, beyond the fact that the Secretary's time has been so fully occupied by public business of the most pressing character that he has not been able to give the law in question the consideration necessary to putting in operation the methods therein contemplated."

It was not long before the members of the Institute discovered that it was not wise to put their trust in American statesmen. A federal building was required for Buffalo, and in spite of the guarantees, the design for it was prepared in the office of the supervising architect. As the design was not above the ordinary official attempts, the directors of the American Institute wrote to say they believed it to be their duty to their profession and to the whole community to protest, "for any structure of the general character of the design, if carried into execution, will be found absolutely wanting in the fundamental elements which go to make a public building, and will be condemned by the community. We therefore respectfully urge that you use your power to prevent the construction of this design." The supervising architect in reply said:—"This communication is of such an unusual and extraordinary character, based on *ex parte* and indefinite information, and so at variance with professional courtesy and good breeding, that, in justice to the A.I.A., I hesitate to believe in its legitimacy, and request that you will kindly advise me by return mail if it has really emanated from the board of directors of the A.I.A."

On February 5 the executive committee of the Institute endeavoured to have an interview with the Secretary. Mr. Carlisle would not meet them, but referred them to Mr. O'Rourke, with whom the committee refused to have any communication until he had withdrawn his letter, which reflected on every member of the committee. The Assistant Secretary for State, however, gave the committee to understand that the plans for the Buffalo building had been withdrawn, and that the work would rest where it was.

On February 6, Mr. O'Rourke wrote to Mr. Burnham, president of the Institute, and said:—"I shall be much pleased to meet you or the executive committee of the American Institute of Architects at any convenient time, for conference and mutual exchange of views on this subject."

In reply Mr. Burnham said:—"I regret exceedingly that the conference which you propose between yourself and the officers of the American Institute of Architects is impossible. It can only be made so by the preliminary withdrawal on your part of the official letter dated January 17, signed by yourself, as 'F.A.I.A.' and as 'Supervising Architect,' and addressed to Mr. Alfred Stone as 'Secretary A.I.A.,' in which you refer to the document signed by the directors of the American Institute of Architects as 'at variance with professional courtesy, good breeding,' &c."

"I sincerely hope you will withdraw the letter I refer to, and also the copies sent to members of the directorate. I am sure you will gain the esteem of all men of the profession by taking this course."

The next step taken was to appeal once more to the Secretary. Mr. Burnham in his letter said:—

"I now have the honour of taking up the points brought out in the interview with the Honourable Assistant Secretary in Washington on February 5. The gentlemen of the committee of the Institute who were present on that occasion were George B. Post, E. H. Kendall and Charles F. McKim, of New York; Arthur Rotch, of Boston, and William W. Clay and Samuel A. Treat, of Chicago. Each of them would be regarded

as a competent critic of architecture, and there can be no doubt as to their fairness.

"The design of the Buffalo building, which is so often referred to in the above papers, was examined by them with a view of suggesting changes to bring it up to the proper standard for a structure of that nature. Their unanimous conclusion was that such a course was not possible; that to make the present design satisfactory would involve changes so extensive as really to produce a new design.

"The question the people of Buffalo now ask is not 'Can the Act of '93 be improved?' They know that as it stands you have the power to order a competition for their building. They have the opinion of the board of directors of the Institute that the design made in Washington is improper, and they believe this themselves. They ask you to take the step which the law authorises, thus insuring a noble monument which may be for ever a pleasure and pride to the city. This competition can be carried through in an exceedingly short time if you will order it. The exigency of the case would be considered by the architects, and they would be willing to prepare much quicker than could ordinarily be expected of them.

"I have already said that the architects themselves will agree to furnish a full and satisfactory competition for this special case without cost to the Government. We are also ready to assist the Government in the arrangement of a code for the competition.

"I note by the public press that the supervising architect recently informed Assistant Secretary Curtis that it will take three years and a half for his office as now constituted to design the buildings already authorised. If this be approximately true, the retaining of a number of the most able architects of the country to assist him is imperative and urgent.

"I now have the honour to request you to name a day when the executive committee of the Institute may be heard by you on the questions covered by this memorial. We offer to assist in placing its architecture upon the footing demanded by the country. We will serve without pay, giving our best endeavours to the work."

In spite of the economical attractions of the President's offer, Mr. Secretary Carlisle was not to be tempted. In acknowledging the receipt of the memorial, he informed Mr. Burnham:—"It has, therefore, been determined to proceed with the work in accordance with the design prepared by the supervising architect, which is satisfactory to the department, and which it is believed will, when carried into execution, meet the approval of the public."

Another protest was at once sent by the President of the American Institute. In the course of it he said:—"The working of the supervising architect's office is not a free-masonry requiring special trained adepts to undertake it. It is a simple organisation which any good business man, with a knowledge of building, can understand or operate, and I venture to assert that if the goodwill to do so were present in your department, the organisation of the office on the basis of the present law, which gives you the right to employ the best designers in the country, could be brought about in a few weeks, and that it would then be better than the present one.

"I do not forget the protestations of the supervising architect of his readiness and anxiety to do all in his power to forward this important matter. I am aware that you yourself stated to the gentlemen of the Institute that you were in hearty accord with them on the subject. I am also aware that twelve long months have since passed, during which nothing whatever has been done in your department looking toward the carrying out of this law, except at the eleventh hour, when Mr. Secretary Curtis stated to a committee the four principal obstacles which were in the way.

"The obstacles are not real ones and never were, and after carefully looking over the ground I can see no others, although I am tolerably familiar with the workings of the supervising architect's office in Washington, and entirely familiar with the law on the subject.

"You now inform us, in effect, that the law must be amended before you will act under it. I can see but one amendment which is needed to insure the satisfactory working of this measure, *i.e.* the introduction of a clause ordering the Secretary of the Treasury to carry out its plain intent and purpose and not leaving it to his discretion."

The last words nettled the Secretary, and on March 12 the correspondence comes to a close with the following curt epistle from Mr. Carlisle:—"Your very offensive and ungentlemanly letter of the 9th inst. is just received, and you are informed that this department will have no further correspondence with you upon the subject to which it relates, or any other subject."

Nobody would be surprised if the officials of an English department amused themselves with playing with any of the architectural societies, but it was supposed that the American Institute of Architects was possessed of some influence which would insure respect in a Government office. It is now evident that architects in the United States are, in the eyes of officials, as unimportant as their brethren in England or France.

The members of the American Institute have been under a delusion about their position, for not one of the workmen's societies in the United States would have been subjected to so much humiliation over a question of employment. The rejection of the services of architects, although offered gratuitously, cannot be advantageous for the profession among men of business. It is holding out a flag of distress, and hard terms are sure to be demanded.

NORWICH CASTLE.

IT is uncertain, says the *Eastern Daily Press*, when the Castle Museum will be opened to the public, but when that event takes place the citizens will find that a remarkable transformation has been effected. Though the castle has undergone many curious vicissitudes in its progress towards a museum, it has known no more striking change than that which the last few years have witnessed. From being a prison house, it becomes from henceforth one of the most delightful resorts for the studious and the curious that the provinces can boast. It was never a fitting thing that the most commanding site in the city and the most interesting of our ancient remains should have been associated with the punishment of crime. It was a narrow piece of State economy to turn the unsentimental bricklayer loose among the Norman arches of a feudal stronghold in the endeavour to make it answer the requirements of the penal code. Compared with only a few years ago, the present order of things suggests a delightful contrast.

To rescue the structure from its baser uses and apply it to the purposes of a county museum was a vigorous idea; indeed, at the outset it bore an aspect of extravagance and impracticability. It was not surprising, therefore, that the public mind did not embrace the proposal all at once. The late Mr. J. Gurney, apart from whose generosity and encouragement the museum scheme would never have been floated at all, at first utterly disbelieved that the old county prison could ever be made to serve the purposes to which Mr. Boardman proposed to apply it. The prison governor, Mr. Dent, likewise entered a vigorous demurrer. The architect, however, was able to demonstrate the feasibility of his plans, and thenceforth the notion seized upon the public sympathies. It is needless to record how Mrs. Gurney, with generous loyalty to the wishes of her deceased husband, came down with 5,000*l.* out of her private fortune, and how others followed in her train. To record all the changes which the architect has devised would be to turn this notice into an architectural catalogue, and even then the public mind would not be enlightened, for the general plan of the castle, perhaps, is not clearly understood. To be plain and brief, the whole enclosure is, roughly speaking, circular; the keep, which abuts on the outer circumference, occupying about one-third of the entire area. Within the battlemented walls, but separated from them by a footway some dozen feet wide, there is a range of six plainly-built rooms connected with each other by Tudor corridors. These rooms could not have answered the museum scheme much better if they had been designed with that object expressly in view. The cells with which they were filled have been swept away, and now the walls are lined with smart new air-tight cases almost ready to receive the museum collection.

To the average visitor the keep, of course, will be the principal seat of attraction. The interior now forms a fine, spacious hall, with a glazed roof. Round the best-preserved parts of the old unrestored masonry runs a substantial wooden gallery. We need not speculate here on the uses to which this handsome chamber may come to be put, but there is no doubt that its associations and other advantages will speedily bring it into demand. The removal of the clumsy brickwork with which the ancient masonry of the interior was disguised has been carried out with the most successful results. So precious are the architectural treasures brought to light that some of our local antiquaries have become morbidly fearful lest the wall should suffer from the process of decay. It has therefore been proposed that the whole of the stonework of Norman origin should be indurated with some protective preparation. Mr. Boardman, however, has decided to recommend no such process at present. He has paid a special visit of inquiry to the Tower of London, but it seems that induration is not adopted there, nor is it regarded as at all necessary. The excavation of the dungeons beneath the keep has brought to light little or nothing of archæological interest, if we leave out of account the crude reliefs on the walls. In one instance there is a well-defined cross with a roughly-drawn human figure upon it. In the opinion of those who are learned in such things, this humble expression of Mediæval devotionism may well date back to the time of King Stephen. Across the gulf of seven or eight centuries the tender faith of a prisoner in a feudal dungeon shines star-like upon us.

When we pass by an abrupt transition from the subject of feudal keeps and dungeons to the electric light and the Blackman fan we almost feel ourselves guilty of some ludicrous

anachronism. And yet we shall only be recording what has actually taken place. It is really true that the whole of the interior has been illuminated by the electric light, and it is equally true that the air within the walls will be renewed by means of that marvellous contrivance, the Blackman ventilating and heating fan. Notwithstanding the halo of romance which poets and novelists have thrown about the times of Hugh Bigod, the suburban jerry-builder of the nineteenth century could give him some useful tips on the score of health and comfort. There are two sets of lavatories at the castle such as King Stephen in his wildest dreams of magnificence could not have foreseen. These time-worn fanes and fortresses are sweetest when modern science and resource have civilised them somewhat. The barbaric splendour of the past is never so splendid as when viewed through the medium of the unenlightened imagination.

SOCIETY OF SCOTTISH ARTISTS.

THE annual general meeting of the Society of Scottish Artists was held in Edinburgh on the 6th inst. Mr. Robert Noble, A.R.S.A., who presided, in proposing the adoption of the annual report, expressed regret that the year had been an extended one, but added that that was through no fault of the Council. It was his duty to apologise and explain that it was all owing to the change of the date in obtaining the National Gallery rooms in which to hold their exhibitions. They were at present in communication with the Board of Manufactures for the grant of the rooms to hold their third exhibition, and as the Board had expressed a desire that it should be held in the summer season, they had made application for the months of September and October. Failing these months, he could only recommend the summer of 1895 for their next exhibition. However, to go back again on the report for the past year, he could not but consider it a highly satisfactory statement, and he was sure they would confirm that opinion. Again they showed a surplus, which, added to their previous year, made 454*l.* And when they considered the unparalleled depression they were passing through, which affected art as well as trade, and taking into account the unfavourable change of date for holding their exhibition, they had still a sure guarantee that, on the lines laid down for guidance, the Society of Scottish Artists could finance successfully an exhibition at either date. The depression affected the sale of pictures, and their revenue on that account was considerably less. They had every reason to be proud of the artistic standard attained in their past exhibitions; they should therefore see that the next was not a bit behind. There was no doubt that much depended on the taste and tone of an exhibition in making it a success; and as they had hitherto made that a special feature, and might claim originality on that score, no matter what might be said to the contrary, let their taste, therefore, always be artistic. In their loan collection they made no effort to change the schools represented from that of the previous year, and gave great satisfaction to members as well as the public. Nothing, for instance, could be more varied in style and treatment than the examples of the Barbizon school in comparison with that of the more modern Frenchman "Aman Jean"; or, coming nearer home, to the different treatment of Sir John Millais, the late Mr. Pettie, and many others of their own school. He trusted that in the years to come the exhibiting of those masters would have a healthy influence on the younger men of the Scottish school of painters. Whilst thanking those lenders of pictures, he could assure them that those gentlemen were only too pleased to assist the Council, the more so after being told of the aims of the Society. He expressed the hope that a still greater effort should be made by their professional members to fulfil the second aim of the Society. Already they had done well, but year after year there must be an advance in their efforts; the public as well as lay members would look for it. The report was adopted. The following officers were elected:—President, the Marquis of Huntly; vice-presidents, the Lord Justice-General, Sir James D. Linton, P.R.I., Sir John E. Millais, R.A., and Mr. W. Q. Orchardson, R.A.; chairman of council, Mr. R. B. Nisbet, A.R.S.A.; vice-chairman, Mr. Duddingstone; secretary, Mr. R. H. Christie.

OLD AND NEW EDINBURGH.

A PAPER was read at last week's meeting of the Edinburgh Architectural Association on "The First Wall of Edinburgh, or the King's Wall, and some evidence relating thereto," which was written by Dr. Millar, F.S.A. He said that Maitland asserted the King's wall was built after 1450, but from a charter of James II. it appeared that this wall formed the boundary of houses on the south side of the High Street at an earlier date. The line of the wall, as shown with the aid of a limelight view, passed in almost a direct line from the Castle

to the Netherbow, its course being through the centre of the block of houses on the south side of the High Street. Portions of the wall were discovered early this century at Parliament Square. This wall existed from the earliest period in the history of the town.

Mr. G. S. Aitken, architect, read a paper on "Modern Edinburgh," discussing the precise point at which James Craig, the pioneer in the planning of the New Town, commenced his work. The lecturer said the fact usually stated was that the first house erected was in Rose Court, George Street, by John Young, and that it secured to him the premium of 20*l.* offered by the magistrates to whoever should build first, the foundation-stone being laid by Craig, October 26, 1767. Mackay, in his "Barony of Broughton," mentioned Thistle Court, and gave the date as 1766. In an early map without date, published by Ainslie, which he stated was a copy of one in the possession of George Paton, of the Customs, and dedicated to Lord Provost Steuart, thus fixing it at the years 1780-81, the only houses shown immediately behind St. Andrew's Church are the *vis-à-vis* two-storey blocks still standing in Thistle Street, with gardens or forecourts separating them, and numbered 1, 2, 3 and 4. In early days No. 2 was the abode of Sir John Gordon, and No. 4 of Sir Alex. Don, of Newton Don. Another authority stated that the first house built in the New Town was No. 1 Princes Street, next the Register Office, and that it was erected by John Neale, a haberdasher, who took possession in 1774, but discouraged by want of patronage in his new quarters, returned to his original place of business in the Old Town. It was further stated that being the first house erected it was exempted from all burghal taxation. This might mean that it was the first erected in Princes Street, for it was evident that priority of date settled the question in favour of the Thistle Street house. The early houses in Princes Street, it was said, had no doors to the main thoroughfare, but were entered by common stairs from the mews' lanes. This might quite well have been the case. As Craig's plan indicated no stables at the backs of the houses, the approach from that side would therefore be unobjectionable. The first part of the New Town begun was the eastward end, but in this quarter occurred no buildings of any special interest except Sir Laurence Dundas's house (which was designed by Sir William Chambers), and the corner blocks that flanked it in the line of St. Andrew Square. Of these two blocks that to the north, it had been suggested, corresponded with a design in one of the Adam's volumes in the Soane Museum of a house for Mr. Andrew Crosbie, advocate (the original of Pleydell in "Guy Mannering"), but the fact was that the columns and mouldings did not accord with those usually employed by Robert Adam; indeed they were not good enough to be his work, and it was moreover unusual for him to use an order rising at once from the ground floor, although his father, William Adam, did so, as might be seen at Hopetoun House and Airth House. The most interesting and scholarly examples of the early phases of New Town architecture were to be found in the façades of Charlotte Square, and it would be well if, recognising this, the proprietors jealously guarded these treasures from being tampered with, or if it was necessary that alteration should be made, arrange that it be done with the utmost good taste and in a conservative spirit. There was no portion of any of the four sides which would not repay careful study; each side was arranged on the central block and wing system, and one strong point of merit was that the roofs, contrary to practice in Classic architecture at that time, were made to form a visible and agreeable part of the composition.

ARCHITECT'S FEES.

AT the Tenterden County Court, the case Ernest Hadden Parkes, architect, *v.* Charles Thomas Pizey, vicar of Smallhythe, was heard. Mr. D. C. Bartley, barrister-at-law, instructed by Mr. J. A. Collins, appeared for plaintiff, and Mr. De Mortimer-McIntosh for defendant. The action was for 26*l.* 5*s.* for professional charges by plaintiff in regard to work done for the restoration of Smallhythe Church. For the plaintiff it was stated that plaintiff had considerable experience in church restoration work and had carried out the restoration work of Wittersham Church, where in July 1892 he was met by defendant who spoke to him about proposed alterations at Smallhythe Church, and subsequently wrote asking for plaintiff to go and see him with a view to placing the matter in his hands. On August 15, 1892, he had an interview with defendant, and they went together to the church. Defendant pointed out the various proposed alterations, and instructed him to prepare plans. The question of raising the money was also discussed, and defendant stated that he hoped to get some of it by subscription from neighbours, and also wished to get grants from the Diocesan Church Building Society and the Incorporated Church Building Society. Plaintiff knew that to obtain these, plans would have to be submitted to the societies, and he discussed the subject with

defendant. For this interview plaintiff had charged 1*l.* 1*s.* On August 25, 26, 27 and 29 and other occasions plaintiff went to the church to take the necessary measurements to enable him to prepare the plans. For this he had charged at the rate of 2*l.* 2*s.* per day, making a total charge of 9*l.* 9*s.* in respect of this, although he said he had a right to charge 3*l.* 3*s.* per day, according to the scale on which architects usually based their charges. He showed defendant the sketch-plan, and was to prepare a plan to carry out the ideas indicated in the sketch-plan. In the meantime plaintiff prepared detailed plans, and he charged 5*l.* 5*s.* for preparing plans to submit to the societies. He subsequently wrote to defendant several times with a view to the work being commenced, but could not get any definite answer from him. The total cost of the restoration plaintiff estimated at 350*l.*, on which he claimed to be entitled to make a charge at the rate of 3 per cent. A claim was also made for 1*l.* 1*s.* for incidental expenses. As he could get no definite answer after waiting a long time, with a view to bringing the matter to a head he finally wrote on November 6, 1893, for payment of 10*l.* on account, received no answer, and subsequently the present action was taken. Evidence was also given to the effect that the charges were reasonable.

For the defence it was contended that the question of proposed work was a very small matter, and that what was contemplated was removing some old pews and replacing them by slips and reflooring. Several other matters were mentioned, but only by way of conversation. Defendant did not think the cost would exceed 150*l.* Defendant was greatly annoyed at the application for payment for 10*l.* on account before an account had been rendered, and it was contended that the only instructions given plaintiff were to prepare a plan for the defendant's approval, and that defendant never had approved of the plan.

His Honour, in the course of his summing up, said that it was necessary for plaintiff to make details of the measurements, that he was entitled to some remuneration for the work he had done, and he was of opinion that the sum of 9*l.* 9*s.* was a reasonable charge which should be paid. With regard to the charge of 10*l.* 10*s.* which had been based on percentage, His Honour was of opinion that this would have been far better to have been dealt with as a question of time, and for that item he allowed 6*l.* 6*s.* As to the incidental expenses he did not think he could allow them. His Honour declined to allow the charge of 5*l.* 5*s.* for preparing plans to submit to the societies, which he held to be premature, and that plaintiff should have waited for instructions before preparing them. Judgment for plaintiff for 15*l.* 15*s.* with costs. On the application of Mr. McIntosh the amount was made payable by two monthly instalments.

GENERAL.

The French Artists who exhibit in the Champ de Mars have resolved to avoid sending works to the Antwerp Exhibition, as they are not represented on the committee of organisation equally with the artists of the Champs Elysées.

The Hanging Committee of the Royal Academy for this year are Messrs. Sant, MacWhirter, Woods, Moore and Davis for painting, Mr. Alfred Gilbert for sculpture, and Mr. Waterhouse for architecture.

Sir Benjamin Baker, C.E., has reported that the cost of raising the temples at Philæ to a secure height would be 150,000*l.*

Alternative Designs are in preparation for the County Offices, Wakefield, plainer and cheaper buildings being desired by the County Council.

Members of the Surveyors' Institution have formed themselves into a committee in order to raise funds for a testimonial to Mr. Julian C. Rogers, who has filled the office of secretary during twenty-five years.

An Exhibition of hammered ironwork was opened at Ironmongers' Hall, Fenchurch Street, on Wednesday, by the Lord Mayor.

The Surveyors' Institution will meet on Monday, the 16th inst., when the adjourned discussion on the paper read by Mr. Howard Martin, at the meeting of March 5, on "The Report of the Local Government and Taxation Committee of the London County Council on the subject of the Rating of Ground Values," will be resumed.

Mr. W. E. Hill, at the meeting of the Liverpool Architectural Society on Monday, the 16th inst., will read a paper entitled "A Few Notes on Mediæval Architecture in the West of England."

Mr. Lancelot Wedderburn has presented to the Leeds Municipal Art Gallery two historical pictures, painted in 1775 by an artist named J. B. Bolab Sen.

The Architect.

THE WEEK.

As Sir FREDERICK LEIGHTON is to be the recipient of the gold medal which was originally intended to reward young students of architecture, he will probably have to pay for the gift by giving advice gratuitously. Although he does not yet possess the medal, the President of the Royal Academy has been called on for an opinion by no less distinguished a body than the scavenging committee of the Bath Town Council. It appears a destructor is about to be set up, and it had to be decided whether a chimney constructed of buff bricks or one of red bricks would be the prettier. Bath has an excellent official architect, but so important a question was considered to require the judgment of Sir FREDERICK LEIGHTON. Although at the present season an Academician has enough to occupy him with his own works, Sir FREDERICK courteously responded. He wrote:—"I have no difficulty in answering your question at once. Rich full-toned red brick grows in beauty through weather, wear, and time; paler material, commonly called white brick, increases in unwholesome dinginess with every week, particularly in the West-country climate. There can be no difficulty, therefore, in deciding which material is the more suitable for a purpose of which one cannot under all circumstances but deplore the necessity." "Much will have more," says the old proverb, and it will scarcely be credited that one of the councillors suggested that the President might paint a picture of the destructor for them without increasing the rates in any way. As the example of the Bath committee is likely to inspire other authorities to obtain opinions without paying for them, Sir FREDERICK will find it an advantage to spend the ensuing months in some distant region.

It is remarkable how many circumstances appear to arise as if for the purpose of keeping up the interest in SCOTT'S novels. This week many people are likely to be engaged in reading "Kenilworth," for the legends on which that romance was based have had their influence on a law case which came before Mr. Justice NORTH. The plaintiff, Mr. SCOTT-HALL, purchased Cumnor Place because he imagined he was gaining possession of an historic property. According to the auctioneer's description, the property consisted of a "freehold dwelling-house, &c., deriving its name from the very historical abbey once standing in Cumnor Park, of which the present property forms part, and referred to in Sir WALTER SCOTT'S novel 'Kenilworth' as the place where AMY ROBSART died." There were other rhetorical flourishes introduced which rather obscured the prosaic facts. The plaintiff was one of those numerous people who somehow imagine that at auctions they can pick up treasures. He saw the "lot," not as it was, but as it appeared in SCOTT'S pages; and, on the supposition that he was acquiring a house the legendary interest of which was enhanced by the occasional appearance of AMY ROBSART'S ghost, he bid 2,010*l.*, and was declared to be the purchaser. Judging by the value of the ordinary property in the neighbourhood the sum might be considered rather high; but, as a man acquires dignity from owning something which belonged to the great LEICESTER, it is only fair he should pay for it. Mr. SCOTT-HALL'S enthusiasm cooled down when the excitement of the auction was over, for it was not long before he discovered that the house did not correspond with SCOTT'S description, and he tried to get out of the completion of the purchase by taking an action to have the contract set aside on the ground of misrepresentation. A judge cannot be expected to save people who allow their imagination and desires to control their reason. Mr. Justice NORTH, in the first place, decided there was no misrepresentation by the auctioneer. In the second place, his lordship declined to believe that the plaintiff was led away by misrepresentation of any kind, not even Sir WALTER SCOTT'S. In the novel the house was supposed to stand on the west side of the church, while the house that was sold stands on the east side. If the plaintiff

had used "Kenilworth" as a guide, he would have found that there was no place for the machinery which caused the death of the favourite. The case failed, and the plaintiff will not have the sympathy of novel readers. Mr. SCOTT-HALL had better make the best of his bargain, and he can be happy in his old home, although it was never used as a prison or for a murder.

It was decided at the meeting of the London County Council on Tuesday to invite competitive designs for some of the dwellings to be erected on land in the Council's possession which is required to be devoted to the accommodation of the working classes. The competition is to be limited to six architects who have shown themselves to be thoroughly competent. The sum of 50*l.* is to be paid to each competitor, and, in addition, a sum of 200*l.* is to be distributed among the competitors at the discretion of the public health and housing committee. The usual commission of 5 per cent. will be paid to the successful competitor in addition to the sums mentioned.

GLASGOW is not a city which a visitor would consider as severely moral, and there are few men who have not heard tourists express their amazement at the laxity which is permitted. It is therefore pharisaic on the part of the authorities to prohibit the exhibition of photogravures which in London and elsewhere have been admired by men and women whose virtue is undoubted. To suppose that such artists as Sir FREDERICK LEIGHTON, Mr. WATTS, Mr. POYNTER, Mr. HACKER and Mr. SOLOMON, the painters of the original pictures, would pander to a depraved taste, is absurd. We doubt if the austere Bailie NICOL JARVIE or his worthy father the Deacon would make so ridiculous an exhibition of themselves as the present police authorities. If works like the *Bath of Psyche*, *Diana and Endymion*, the *Visit to Esculapius*, *Syrinx*, *Orpheus* and *The Judgment of Paris* are unfit for exhibition, what is the advantage of expending money on art galleries in Glasgow?

THE exhibition of wall-papers and other products for wall decoration at Messrs. JEFFREY'S factory at Islington is most interesting. It is not often such excellent design is combined with perfect manufacture. By commissioning the ablest artists in decoration and employing the most enduring materials, Messrs. JEFFREY have gained success that some years ago would have appeared to be unattainable in England. They have been no less fortunate in extending their operations. From embossed paper they have gone on to embossed leather and copper. Their *portières* in leather will more than sustain a comparison with old Venetian work, and, judging from the appearance of early samples, it is evident that time increases the beauty of them. The panels in *repoussé* copper are surprising not only from their delicacy, but on account of their moderate price. Neither France nor Germany can show better adaptations of the two classes of work, and they merit to be extensively employed. The enterprise which is seen in the successful experiments in leather and metal continues to be as marked as formerly in papers. Any of the new silk flocks is worthy of being hung in the boudoir of a princess. Among new papers we may mention the "Piccolomini," which is the most vigorous design we have seen from Mr. LEWIS F. DAY, the "Seed and Flowers" by Mr. WALTER CRANE, the large "Vine" by Mr. SUMNER, the "Venetia," the "Coronæ Vitæ," the "Tree" by Mr. WILSON, and others by Mr. VOYSEY and Mr. STEPHEN WEBB. Mr. MUCKLEY'S skill as a flower painter has been turned to account, and there is a daring ceiling paper with geometrical patterns in brilliant colours, by Mr. VACHER, which is especially deserving of a trial. The enumeration of designs is, however, an inadequate manner of suggesting the character of the remarkable collection which is to be seen at Messrs. JEFFREY'S. The liberal treatment which artists are insured, and the extraordinary power of organisation which is seen in the reproduction of their designs have been already rewarded, but they will always be sure to merit the appreciation of architects.

STYLELESS ARCHITECTURE.

BOOKSELLERS and publishers have a sort of superstition about the advantages of a resonant style, although they are chary of producing works in which it is exemplified. In the market the needs of busy people who have little time for reading have to be met, but even the purveyors of what is known as light literature profess to have a liking for stuff of another sort, and the only sentences which they can quote are a few which were written in days when people had leisure to linger over a page and to store their memory with favourite passages. The worthy publishers who heard Professor GOLDWIN SMITH on Saturday night after their dinner must have been shocked. They saw before them a man who had been trained in Oxford, and was imported into America as a representative of the academical manner of looking at life. Yet at an hour when, under the influence of good wine, publishers are apt to imagine they are the guardians of what is best in literature, he ventured to wound their tenderest susceptibilities. The Professor hazarded the declaration that the absence of stylists like MACAULAY and CARLYLE was not so great an evil as had been supposed, nor was that the worst of styles which was no style at all. What was to become of the Row and Albemarle Street if a belief of that kind were to spread? It would mean that people would become still more disposed to read newspapers, periodicals and other unbound things, and would avoid books. For in a publisher's eyes the great difference between books and other products of the printing-press is that one class is supposed to possess style, while the other is deficient in the quality.

What is generally taken to be style in prose was well described by COWPER, the poet, as setting periods to a tune. If you can keep up the tune long enough to make it familiar to the ear much will be forgiven. You may omit the name of an authority from whom you take a text, if, like JOHNSON, you describe him as "an ancient poet unreasonably discontented with the present state of things, which his system of opinions obliged him to represent in its worst form." In conversation one would say "LUCRETIUS," but prose that is stylish must not resemble ordinary speech. Or you may define a net as "anything reticulated or decussated at equal distances, with interstices between the intersections," for as long as we gain style we may readily sacrifice clearness. JOHNSON'S volumes used to be given as presents to young clergymen with literary ability, in order that they might acquire from them an impressive way of instructing rustic congregations, and "the Trade" has still faith in their virtue. CARLYLE and MACAULAY are also admired for their grandiose manner of saying things. A man could not hope to succeed if he wrote to his lady-love or to a client in the manner of either of them, and no vestry or local board would listen to him if he attempted to explain plans or to excuse the ordering of a few extras by an imitation of their language. MACAULAY endeavoured to bring down his style to an everyday level by constant reading of Madame DE SEVIGNÉ'S letters to her daughter, but he could never gain elasticity. For him, his models and imitators, it was easier to mouth a speech than to speak it trippingly on the tongue.

The stylists are, to some extent, responsible for the belief which now prevails that a negation of style denotes some virtue. But other causes have aided. In the first place people are busier, and they have not the time to hunt for a thought in a heap of words. Then they have lost faith in many of the standards which were supposed to be infallible. GIBBON at one time was a sort of classic; now it is recommended that his pages should be handed over to schoolboys to be translated into English. His contemporary ROBERTSON was supposed to be no less stately and more diversified, but, according to WORDSWORTH, he was unable to write English, and all his sentences are cast in two moulds. The number of models of style in composition that have ceased to be worth reprinting is marvellous. Over a century ago HORACE WALPOLE said to somebody who consulted him on the subject, "Style, is it that you want? Go and look into the Plain Papers for a style." With all his frivolity, there was no submission of what was readable, and he preferred news-

papers to books because they were not pedantic or affected. It was in a similar spirit that DE QUINCEY said, and he was not an enemy of the English masterpieces, "The pure racy idiom of colloquial or household English must be looked for in the circles of well-educated women not too closely connected with books." In their circles, as in the newspapers, the old pomposity is out of place, and the thoughts which are uttered must be free and belong to the time. What is said is no doubt fugitive, but that is not the least charm, for the brightest is always the fleetest.

All this may appear to be true as regards literature, but dare we say that the absence of a formal style is as little to be deplored in works of art? At any rate, it will hardly be denied that the public, who are the patrons, the upholders, prefer the informal to the formal. In painting this is especially seen in France. Among the people in that country it is acknowledged there is a larger proportion who are competent to judge and to form a definite notion of the qualities which merit approval in a work of art than elsewhere. Now it is notorious that every Salon exhibits a further departure from the subjects and treatment which at one time were held in reverence. Where are now to be seen the examples of *le style sublime*, or *le beau style*, or *le style gracieux* which were once common in every exhibition? It may be said that the majority of the paintings which were supposed to represent those styles were not worthy to be accepted as works of art. That argument does not meet the case. Bad as the old works may have been, they were evidence of aims which have ceased to be effective. Artists no longer seek after the sublime because they doubt their power to create anything which is superior in character to the life that is around them. They could again employ the old-fashioned rules for producing beings of the kind, but if patrons are not exalted before the figures, like their predecessors in the old days, where is the advantage? Efforts are made to convince all classes in France about the advantage of believing in the classics of art and literature, but fate is stronger than any official course of education. When he ceases to be a student the Frenchman emancipates himself from what he believes to be a thralldom, and the things to which he was compelled to show reverence become more obnoxious because he is confident the change in his feelings comes from knowledge.

In England we can see the signs of a like tendency, although as yet it has not been so marked as in France. English architecture at the present time may be said to correspond with English literature. The respect for old literature has not expired among us, but a statesman endowed with a redundancy of words would not in our time, like FOX in the last century, when composing a book, reject every word that was not sanctioned by DRYDEN'S usage. A seeker after a style that will be "familiar but not coarse, and elegant but not ostentatious," no longer expects to secure it by giving his days and nights to the volumes of ADDISON. He knows it is necessary to do much more. The world does not want weak imitations of DRYDEN or ADDISON, of MACAULAY or CARLYLE, while the originals are to be obtained. It is only writing with a distinct, an uncommon character which is sure of a welcome. A new style that is worth notice is a gift which is not to be attained by labour alone, and for the majority of writers it is wiser to think more of substance than of manner.

The modern architecture of England also exemplifies that one or two ancient stylists cannot any more look down on a crowd of worshipping architects and clients. The disadvantage of the absence of that sort of idolatry has been impressed on us all. No lawlessness is supposed to bring about more momentous consequences. Now that chapels and gate lodges are rarely made to resemble classic temples, when colossal porticos are not accepted as indispensable in ecclesiastical and secular buildings, when the outside of a building is not necessarily at variance with the interior, no claim can be made to the possession of an architectural style, and when that is absent chaos must be approaching. Those who set up classic standards were, however, less rigorous than the Gothicists. As there can be little that is common between a Greek or Roman temple and an English church or other public building, some latitude in treatment of details was tolerated, but as Mediæval and modern buildings are supposed to be related closely, the

safest course for a designer of the latter was to forget that he was endowed with imagination and stick to precedent. At every step he was liable to be stopped and made to produce authority for his action. Ancient Egypt could hardly possess a more tyrannical body of arbiters than the Cambridge Camden Society. Rectors and curates naturally assumed they were possessed of its power to distinguish right from wrong in all things relating to masonry construction, stained-glass and needlework. A style was established for a while, but as it was insincere (for anything, however rational, that was not likely to secure the approval of the Society was sacrificed), and expediency became the dominant principle, it could not live long. It was often of little consequence whether the liberty of the men who derived advantage from submitting to the Society was renounced or not, but they seemed to find a grim satisfaction in displaying the zeal of converts by destroying all evidence of the exercise of liberty at an earlier time. Restoration thus became an effort to impart a fictitious style to what was old, and it was more ridiculous than the attempts to modernise CHAUCER, SHAKESPEARE and MILTON, for meddling with the buildings was to destroy their character. If the men who were inspired by the Cambridge Camden Society were less confident in the infallibility of the council's canons, much would have been preserved for the delight of succeeding times, but we suppose moderation is not to be expected from the upholders of any kind of style.

It can hardly be claimed that we possess an architectural style at the present time in England, that is, if by style is meant the utmost fidelity to precedents or the perpetual repetition of the characteristics of a model. Whether inspiration is derived from England, Holland, France or Germany, there is commonly something added or done which indicates the individuality of the architect. It is often said that the addition is not always an improvement, but whatever is done by a man's hand can be made the subject of adverse criticism. Another allegation is that the class of building in vogue has no right to be called a style. But whether it is a style or a medley, it gives more satisfaction than styles for which purity could be claimed. There are fewer complaints from owners and occupiers about the shortcomings of Free Classic than were heard during the Gothic revival. With all its æsthetic defects, there is no necessity that everyday requirements should be sacrificed to enhance the exterior dignity of a Free Classic building. Clients may be told that the freedom means an irreverential way of dealing with forms which time had sanctified, but they would be disposed to be more satisfied with the experiments on that account.

The endeavour to imitate closely either Classic or Mediæval buildings corresponded with the efforts to use a dead language for everyday affairs. Ecclesiastics who were bound to employ Latin were not long before discovering that Ciceronian purity must be given up. Clerical compositions will consequently not bear comparison for style with the writings of Romans who were inferior to CICERO, but if the style was imperfect, it was better adapted for documents which related to business. When, in our time, Latin is employed, it is indispensable that restrictions must be put on the thoughts, and in consequence the occasional exercises of high ecclesiastics and university orators in that language are only an exhibition of elegant trifling. In the same way when the grand style of English is attempted there is a loss of animation. The History by FOX, which is made up of DRYDEN's words, will not bear comparison for power with his speeches, and Professor GOLDWIN SMITH was probably recalling his sufferings under imitations of MACAULAY and CARLYLE, when he testified to the advantage of compositions in which there was no aping of stateliness. The thoughts which are not to be expressed in language that may be called styleless can hardly relate to this world, and it is no less true that the needs of public and private life in our time can be met by architecture which, without having the grandeur and purity of the Greeks or the soaring ambition of the Mediævalists, has that elasticity which makes it equal to the novel purposes which are so constantly arising.

CURRENT ARCHITECTURAL STYLES.*

THE title "current styles" somewhat imperfectly expresses the object of this paper. To do justice to a description of the current styles of architecture, at least in these days, would be altogether beyond the scope of a short paper, and, moreover, while extremely interesting, and to a certain extent profitable, it is a question whether, in the limited time at our disposal, in a convention of architects gathered from different parts of the province, the opportunity cannot be better employed. The object, then, will be not so much to attempt a full description of the many styles now prevalent as to briefly review some of the more important of them; to endeavour to look beneath the surface, and, if possible, ascertain the fundamental principles underlying architectural style, and from our investigation to deduce some conclusions as to how real progress may be made in the achievements of a profession than which there is none nobler in the realms of art or science.

The frequency with which, in matters pertaining to architectural design or buildings, the public propound to one the question "What style is it?" would be amusing were it not so often embarrassing. It is embarrassing for two reasons. In the first place it opens up the question, "What is style?"—one by no means easy to define. A thoroughly logical definition of the term is seldom attempted. Gottfried Semper says:—"Style is the coincidence in a work of art with the history of its coming into reality, with all the conditions and circumstances that are casual to its origin." Another authority defines "style" as "the language in which we express our thoughts, the natural expression of our requirements in building." But for the purposes of this paper it is not necessary to go further; these two definitions are probably sufficient to convince anyone that an explanation of the term is not quite so simple as at first it may appear. In the second place, the conundrum arises respecting the building or design in question: "Has it any style, and, if so, what?" The answer to this may be more difficult than the first. True, if the building were a copy of one of the structures of ancient Greece or of one of the scarcely less famous cathedrals of the Mediæval period, it would be easy for the veriest tyro to name its style correctly. Incomparably beautiful, however, in their respective classes as those buildings were, their exact reproduction in modern times is usually deemed a ludicrous mistake. The customs, manners, and conditions generally under which they were erected belong to a bygone age, and, charming as such structures might be to the eye, they would, except in rare cases, be wanting in two of the chief elements of the highest art, viz. by utility and truth. But, for the most part, the buildings on whose style we are called upon to pronounce are of a very different stamp. Erected to fill many requirements, and restricted by innumerable conditions, the average modern erection is of a complex character. In many instances, perhaps the majority, it is more than doubtful whether the building possesses any style at all. In others, the taste and skill of the designer have produced a building having an unmistakable air of character and individuality, but of whose style, in the ordinary sense of the term, we are not so certain.

In proceeding to discuss styles of architecture while we are primarily and chiefly interested in the architecture of our own Canada, we must, without any disloyalty or self-reproach, admit that while we have produced work which in its class compares favourably with that of any country, we are, architecturally, overshadowed on the one hand by the great and wealthy nation to our south, and, on the other, by the head of that mighty empire of which we are proud to form a part, and to the architecture of these two countries let us now direct our attention.

In reviewing current architecture in England, the traditions of the past are so intimately connected with modern work that it may not be amiss briefly to refer to the early history of the art. Beginning with the crude ideas introduced at the time of the Norman invasion, the progress of architecture as it slowly developed into the various phases of Gothic is clearly marked in the buildings which still remain as monuments of English art. With the exit of the Tudor style a new and outside influence can be plainly discerned.

Renaissance forms appear, first of a German and Flemish type, followed later by evidences of Italian and French inspiration, culminating in that grand achievement, the pride of all England, St. Paul's Cathedral. Since then the course of English architecture, at no time a particularly smooth one, has taken it through many vicissitudes. From the Classic to the Gothic, and from there to the Renaissance again, first of one period, then of another, such has been its course. The Gothic revival of the present century, ending perhaps with the erection of the London Law Courts by Street, was the last of anything approaching a uniform style. Since that time a spirit of eclecticism, the doctrine of selection, has reigned supreme. Every architect has felt free to choose this or that style as his

The First Portion of a new church, Port Glasgow, designed by Messrs. Pugin & Pugin, is to be started immediately.

* A paper read by Mr. Grant Helliwell at the Convention of Architects in Toronto, and published in the *Canadian Architect*.

fancy dictated, and the result has been an infinite variety of forms. This system prevails in England to-day, so that the term "current styles," as far as British architects are concerned, is a most comprehensive one. To those few men gifted with exceptional talent this has been no particular drawback. It has developed in a special manner their individuality. This is markedly apparent in the work of Norman Shaw, whose buildings, familiar to us all, delightfully charming in their scholarly picturesqueness, their freedom from conventionality, are a standing testimony to his genius, and yet they cannot be classed under the head of any known style, although possessing that quality in a strong degree. Another master in English art is his contemporary, Waterhouse, whose versatility is not less noticeable than his artistic talents. Although he has perhaps achieved his greatest successes in the Romanesque style, an illustration of which is one of the most noted of modern English buildings, the South Kensington Museum, the Manchester Assize Courts and the Town Hall in the same place, both in the Gothic style, gave him a world-wide celebrity, while his masterly treatment of the National Liberal Club building is an example of his genius in Renaissance art.

Time forbids mention of some of the best recent work by other well-known British architects, designed for the most part in some phase of Italian Renaissance, though by no means wholly in that style. But it is an undeniable fact that, with certain few exceptions, English architecture of the last decade shows little progress.

Interesting and instructing as it is to study the architectural types of English building art, it is with even keener interest and greater profit that we turn our attention to prevailing styles in America; for though bound by ties of kinship and political sovereignty to the mother land, in all those conditions which affect the subject of our discussion here, we have much more in common with our near neighbours on this side the Atlantic. We have the same climate and practically the same building materials, and even in our modes of living, our methods of business, and all the environments of national life we are more closely allied to them than to our honoured head. So that the consideration of current styles in the United States may apply equally to Canada, and for the purposes of this discussion we will consider both countries as one.

Any review of American architecture, apart altogether from the ancient buildings of Mexico, is necessarily brief, being of such recent beginning as almost to deny it a history.

A nation of Anglo-Saxon origin, and that not so very far back, nothing worthy of the name of architecture in its buildings dates over two hundred years, and until comparatively recent times it has followed so closely in the lead of England that what has been said of the latter country is quite applicable to the new land. About the time of the birth of the Republic a modified Classic style prevailed, now known as the Colonial, and many of the buildings of that era still remain to testify to the chaste and simple beauty with which they were clothed. But after this a decided retrogression took place, and for the greater part of a century few, if any, new buildings were erected having any claim to style. It was not until the beginning of the last quarter of this century that a distinctly new era in the architecture of the western world set in. That the restless vigour and energy so characteristic of the American people, and which in every other line has forced its achievements to the front, should remain quiescent in matters architectural, was not to be expected, and about the time above mentioned the bonds and shackles of traditional art were thrown off and an advance made into new fields of effort. The progress made has been most marked. Doubtless to the late H. H. Richardson more than to any other single individual is due the credit of the appearance, not of a new style, but of a new principle in American architecture. Trained in the modern Renaissance as taught in the schools of France, he early broke free from the limits of that style, and with his strong individuality took up the study of the round-arch architecture prevailing in Europe prior to the Gothic era, commonly known as Romanesque. In the hands of such a master work was produced which soon attracted the attention of his contemporaries and of the public. He above all men in his generation was the brightest example of that rare genius which can perceive and evolve the hidden beauties and possibilities of the work of past ages. Without slavishly copying, he was able to draw inspiration from every source and adapt it to the varying requirements of his art, and thus produced work which, while it bore the stamp of his own personality, challenged by its beauty and dignity the admiration of all beholders. It is impossible to say to what degree of perfection, had he lived, he might have carried his chosen style. Apparently his mantle has not fallen on any of his successors. True, the influence of his work has been felt far more since his death than while he was amongst us. Like a tidal wave the fashion—for so we may call it—for Romanesque swept the land from ocean to ocean. Many large and attractive buildings were and are still being erected in that style. Some enthusiastic but superficial observers loudly hailed

it as the long-called-for American style. But it was short-lived. Richardson had many weak imitators, but few true followers; they copied the forms, but with the underlying principles that guided the master mind, with that power of adaptation, that fulness of resource possessed by him they were unendowed. What was the result? Buildings, said to be Romanesque, rose by the thousand all over the continent, and the noble and dignified round-arch style was deposed from the lofty throne on which its greatest exponent had placed it to a position almost of contempt. As a consequence, those who did appreciate its charms and possibilities, and who, according to the measure of their ability, were thoughtfully and successfully working out the problems committed to their hands, forsook the style entirely and sought new *motifs* from other sources. Their methods of study and differences of taste led them in various directions; the spirit of eclecticism prevailed, and is still dominant.

There had been, even when the Richardsonian movement was at its height, some few men who had never inclined to the popular style; educated like him, in the French schools of architecture, thoroughly trained in and imbued with Classical art, they had remained true to their early training, and had all along been producing good work of the Classic and Renaissance types. The waning of the Romanesque brought this style of design into special prominence, and the reaction which followed the surfeiting of the public taste with the characteristic freeness and irregularity of the former only served to render the symmetry and precision, the studied proportions, the refined and delicate detail of the beautiful Renaissance the more attractive. The example of these leaders, prominent among whom may be mentioned the names of R. M. Hunt and McKim, Mead and White, was soon followed by other members of the profession, and the new order of things quickly spread. About this time the projected Columbian Exposition at Chicago offered an unprecedented opportunity for architectural achievement, and the selection of Renaissance and Classic styles for its principal buildings and the subsequent successful carrying out of the designs was all that was needed to make these styles perhaps even more popular than the Romanesque in its palmiest days. Still, though no other style or styles can fairly be considered as in the field for popular favour, the disciples and exponents of many other types of architecture are not idle, nor do they fail to find an appreciative and responsive public. The variety of style as exhibited to-day in all classes of buildings is simply amazing. A walk through a residential street in almost any of our cities or larger towns affords a striking confirmation of this fact. Here, for instance, we may see a large imposing residence, the great detached columns in the Ionic or Corinthian order extending through two storeys and supporting the entablature with its low, broad pediment, the wide verandahs, the central doorway with semi-circular fanlight, the broad square-topped windows with moulded architraves, all tending to carry one back to the old Colonial days. Close by is a handsome dwelling with a high steep roof with ornamental eaves, the circular corner bays rising through the several storeys and terminating in a graceful pointed roof, dormer windows, large and high, with slender crocketed pinnacles and sweeping lofty pediment and finial, window and door-openings with ornamented pilasters of slight projection and moulded enriched cornices, all with a degree of symmetry and balance and loftiness strongly suggestive of the French chateau. Across the way, possibly, is a dwelling of Elizabethan type, with coped gables of fanciful and pleasing outline. On a little farther and we pass several residences in what we will call, for want of a better name, the American dwelling-house style—lower storey built of brick or rough-faced stone, above this the walls and gables faced with shingles, sometimes without colour other than the soft silver-grey tint produced by the weather, but oftener stained in some of the pleasing hues of brown or olive; here is a tastefully designed oriel window, there a cosily recessed and deeply-shaded balcony; on one side the simple outline of the roof is broken by a graceful turret or dormer, on another it descends with sweeping curve to form the roof of a verandah. The general contour is certainly pleasing, the outline often picturesque, and there is an unmistakably homelike air about the whole that attracts in spite of many eccentricities and incongruities. It may be called the typical American home, in the production of which American architecture has gained its greatest success. But we are pre-eminently a commercial people, and may naturally look to the buildings devoted to commerce in order to gauge the architectural progress of the day.

In any reference to current architecture in this country the business buildings take a conspicuous place, and we will briefly discuss some of their most characteristic features. And here, as nowhere else, has been brought to our architects a problem for the solution of which there was absolutely no precedent. The tremendous expansion of trade and commerce during the last two or three decades has correspondingly increased the value of land in our great commercial centres, and has necessitated the construction of those enormously high buildings which are the wonder, if not the admiration, of all who visit us. These

buildings of twelve, fifteen, and even twenty storeys have been adversely criticised by some; but was it to be expected that in such an entirely new departure no mistakes would be made? The wonder rather is that such a measure of success as has unquestionably been achieved in the case of not a few of these gigantic buildings should have been attained in view of the extreme difficulties of the problem. In perhaps the majority of instances the designing of these tall constructions, in which the height is so greatly disproportioned to the width, has been so skilfully managed by the disposition of the horizontal lines that the effect of height has been to a large extent obscured. The Romanesque style has been most happily employed in many cases, the usual disposition of the parts, as seen in European Mediaeval structures, lending itself admirably to the requirements of the design, which is commonly composed of a basement boldly and massively treated, comprising two or three storeys, then a central division of several storeys in height, with disposition of arches, the whole composition terminating in an attic of two or three storeys. In the most successful buildings the angles have been admirably managed so as to give the appearance of strength and dignity necessary in structures of such size. Some of the later designs are in the popular Renaissance style, and show a very clever treatment of the problem.

A word as to prevailing styles in ecclesiastical work. In a nation of such cosmopolitan character as America, embracing an almost innumerable variety of religious beliefs, it might be expected that great differences of style would be found, and such is the case. Romanesque, Gothic, Mauresque, Spanish and many other types are represented, though for the most part it must be admitted to the discredit alike of their designers and the congregations for whom erected. In no class of architecture have the Americans so much to learn as in their church buildings. Still in their more recent works signs of improvement are not wanting. The notable competition, a few years since, for the great Episcopal cathedral of New York has done not a little to advance ecclesiastical architecture. Although, as pointed out previously, a great variety of styles prevails in church work, it is doubtful if any are as appropriate for this class of building as the beautiful Gothic forms, and the latest designs of perhaps a majority of our leading architects clearly point to this conclusion.

In her public and legislative buildings, with one or two notable exceptions, America has less claim to congratulation than in other architectural achievements, although here, too, the most recently designed buildings show vast improvement over earlier work. No reference to American architecture is complete without allusion to the Capitol at Washington, a building of which any nation might well be proud. Although it cannot be termed a modern building, yet, inasmuch as the style in which it was built is more popular to-day than when it was designed, a reference to it is specially appropriate here. It is too well known to need description, and it is questionable if a structure of such stately dignity and grandeur will ever cease to exert a powerful influence on the architectural productions of the American people. In this sketch of current American architecture may be seen much that is encouraging. That there is an abundance of life and vigour is evident, and that the character of our work has steadily and rapidly improved is equally apparent. Probably one of the most perplexing circumstances presented to our minds is the great variety of styles seen in our modern buildings, a spirit of restlessness, a lack of definite purpose which would seem necessary for the proper development of our art. Why is this so? Possibly one reason may be the deeper and fuller knowledge of the architectural styles of the past. If this is the case there need certainly be no fear as to the result, bearing in mind the fact that such knowledge includes not only an acquaintance with the form, but what is of vastly greater importance, a perception of the idea, of the principles underlying the outward form. To possess this knowledge and the power to apply it requires patient thought and study, but there is no other royal road to the true development of architecture. Or, again, a reason may be the search after new elements of beauty, fresh and varied forms of architectural expression. This, too, need cause no alarm. Have we not in the works of nature an infinite variety of beautiful forms from the designs of the Divine Architect refreshing and delightful to our senses? Can we wonder, then, in this age of versatility of the ever-changing forms of architecture? The impressive and stately monuments of Classic art cannot satisfy every condition of æsthetic taste, and it is doubtless in response to this characteristic of our nature that we may see in the case, for instance, of Domestic architecture, the signs of a return to the picturesque and quaint beauties of the half-timbered houses of a decade or two since in the very latest designs of some of our leading architects.

We may not look for the formation of a new style; all attempts in this direction have resulted in dismal failure, and this, after all, is not to be wondered at when we consider that the styles of past ages, admirable and beautiful as they are,

were not created in any such way. The degree of perfection to which they were brought was only attained after generations if not centuries of patient and laborious effort, in which the object to be gained was not novelty but a beautiful and natural expression in the best materials at their hand of the requirements of their age. And it is unquestionably in the same way only that any real progress can be made to-day in the true development of architecture.

TESSERÆ.

Early Paperhangings.

WITH the increased production of paper came the idea of applying it to the purpose of hangings for rooms. At first the aim seems to have been directed to imitations of tapestry, and to produce this was employed a material called flock, a kind of woollen cloth chopped small with a machine, strewn lightly with the finger and thumb over the paper, on which a pattern had been previously drawn with fat, oil or varnish, and the different colours and tints being carefully blended, an appearance of tapestry was thus obtained. This method is said to have first originated in England, and was invented by Jerome Langer, who obtained a patent for it during the reign of Charles I., dated May 1, 1634. According to an old French work a manufacture of this kind was carried on at Rouen some ten or fourteen years previously by a man named François, and was succeeded by his son, who continued the business for fifty years after with great success. Originally the material was of an extremely coarse description, and the flock projected considerably from the paper. In the reign of Queen Anne paperhangings were largely imported from China. Jackson, a manufacturer of paperhangings at Battersea, published in the year 1754 a work on the invention of printing in chiaroscuro and the application of it to the making of paperhangings, with fruits coloured in illustration. This book was probably used as a sort of advertisement of his own manufacture, and contains many just and well-sustained remarks, showing a cultivated and properly-directed taste. He purposed, instead of adhering to the old system (for it seems that paperhangings had reached some degree of perfection even then), to employ subjects of more interest than the mere repetition of flowers and ornaments, which prevailed so much that instead of being a principal, as they were, they should be merely an elegant auxiliary to designs of more dignified character, as, for instance, copies of the most celebrated classic subjects, statues and landscapes, and remarks that the persons who could not purchase the statues themselves might have these prints in their places, and thus gratify the taste of the possessor. He also proposed, instead of painting paperhangings in the ordinary way with size colour, that oil should be used, and argued the great durability of oil in comparison with size, and that the beauties of the colours continue as long as the paper can hold together, whereas in a short time the brilliancy of the other is quite lost and requires renewing. About the year 1786 Sheringham threw a new feature into the manufacture of paperhangings. This gentleman, who had spent many years on the Continent, returned about this time to England and established a business in Great Marlborough Street. His enterprising spirit and refined taste led him to engage a number of artists of first-rate ability—such men as Jones, Boileau, La Brie and Fuseli. He was thus enabled to introduce a style of decoration both unique and truly English in its character. He infused into the art a style which for beauty and grace was not equalled before nor since surpassed. Sheringham was indeed the Wedgwood of paper-stainers. About that time the Messrs. Ichardts, who had a manufactory at Chelsea, produced designs of most exquisite workmanship. Besides the mode then generally in use, they adopted a method of applying copper-plates engraved to form the outline, and by an under ground of silver and gold worked up by hand in varnish colours effects of the most beautiful kind were obtained, and they were highly illustrative of the ability of English talent when properly applied.

Influence of Proportion.

No increase of a proportionate object will ever give it magnitude and the sublime; these depend on extraordinary relation and excess of parts and proportions. Several years ago a French giant, upwards of 9 feet high, exhibited himself in London, but so just were his proportions that no one would give credit to his dimensions till they stood beside him; he was therefore accounted a kind of fraud, and the exhibition failed. But had he been disproportioned, his head small, his shoulders high, and his members excessive, he might have succeeded, even had he been a foot shorter. Had the nave of St. Peter's, 77 feet wide, been 90 feet high only, instead of 145; or if we were to suppose a stage raised mid-height and place ourselves upon it, we should be sensible of its vast latitude, and the effect of magnitude would have been produced as under a bridge. The Arc de l'Etoile, from the same reasons,

though as large as the front of Notre Dame (the arch itself is 48 feet by 95 feet, equal to the height of the nave, but of ordinary proportions and great simplicity of parts and members) loses its effect; the *arc monstre* is glorious to the *grand armée*, but not to the arts of their day, and is infinitely less artificial in its combination than the arches of St. Martin and St. Antoine, designed by the accomplished Blondel. If, then, the architect can obtain latitude, he should seek to carry out its effect by quadrate and comparatively low proportions; but if he adds altitude to his latitude, he loses his expense and pains, and he may find too late that half his dimension might have attained the same effect, since proportionate magnitude defeats itself. But as extreme latitude gives the sublime, so does its opposite extreme of altitude. In Cologne and Beauvais, the naves of which are $3\frac{1}{2}$ diameters in height, though scarcely more than half the actual width of St. Peter's nave—limited, therefore, in their dimensions to the usual cathedral width, yet nearly double the usual proportion—the sublime is completely attained, and disproportion again appears to be the efficient cause. But the optical consideration of the visual angle in which these several proportions present themselves is exceedingly important. Thus to the spectator of the dome of the Panthéon, the visual angle is 95 deg., while the same dome raised into the air at St. Peter's is only 30 deg. In the nave of St. Peter's the visual angle is 48 deg., that of St. Paul's Cathedral is 37 deg., while the vault of Cologne is only 22 deg. Since then the effect of magnitude is measured by the number of degrees in the visual angle, the architect will advert to this consideration as of extreme interest. We come, then, to the important conclusion that the sublime and the beautiful are to be found in the proper adjustment of proportions, rather than in dimensions; and we may infer that no increase of scale to the beautiful will ever make it the sublime. But the sublime is of rare occurrence: the use, however, to which these reflections may be turned by the practical architect, under limited means, is remarkably illustrated in the Casino at Chiswick, where the very circumscribed area of the rooms is compensated by their extraordinary height. Lord Burlington has given a nobility to very small apartments which no one could believe on seeing the plan alone, without visiting that elegant work.

The Art of the Homeric Period.

In the Heroic times, the Homeric poems, especially the "Odyssey," attest the refinement and skill to which many of the imitative arts of Grecian civilisation had attained. In embroidery, the high-born occupation of Helen and Penelope, were attempted the most complex and difficult designs; and it is hard to suppose that these subjects could have been wrought upon garments with sufficient fidelity to warrant the praise of a poet, who evidently wrote from experience of what he had seen, if the art of drawing had not been also carried to some excellence—although to painting itself the poet makes none but dubious and obscure allusions. Still, if, on the one hand, in embroidery and upon arms (as the shield of Achilles), delineation in its more complex and minute form was attempted, and if, on the other hand, the use of colours was known (which it was, as applied not only to garments but to ivory), it could not have been long before two such kindred elements of the same art were united. Although it is contended by many that rude stones or beams were the earliest objects of Grecian worship, and though it is certain that in several places such emblems of the Deity preceded the worship of images, yet to the superstitious art of the rude Pelasgi in their earliest age, uncouth and half-formed statues of Hermes are attributed, and the idol is commemorated by traditions almost as antique as those which attest the sanctity of the fœtich. In the Homeric age, sculpture in metals, and on a large scale, was certainly known. By the door of Alcinoüs, the king of an island in the Ionian sea, stand rows of dogs in gold and silver—in his hall, upon pedestals, are golden statues of boys holding torches; and that such sculpture was even then dedicated to the gods is apparent by a well-known passage in the earlier poem of the "Iliad," which represents Theano, the Trojan priestess of Minerva, placing the offering of Hecuba upon the knees of the statue of the goddess. How far, however, such statues could be called works of art, or how far they were wrought by native Greeks, it is impossible to determine. All that Homer calls the work of Vulcan, such as the dogs in the palace of Alcinoüs, &c., we may suppose to be the work of foreigners. A poet could scarcely attribute to the gods a work that his audience knew an artificer in their own city had made. Certain it is that the memorable and gigantic advance in the art of sculpture was not made till about the 50th Olympiad (B.C. 580), when Dipœnus and Scyllis first obtained celebrity in works in marble (wood and metals were the earliest materials of sculpture). The great improvements in the art seem to have been coeval with the substitution of the naked for the draped figure. Beauty and ease and grace and power were the result of the anatomical study of the human form. Architecture has bequeathed to us, in the Pelasgic and Cyclopean remains, sufficient to indicate the massive strength it early acquired in parts of Greece. In

the Homeric times, the intercourse with Asia had already given something of lightness to the elder forms. Columns are constantly introduced into the palaces of the chiefs, profuse metallic ornaments decorate the walls; and the Homeric palaces, with their cornices gaily inwrought with blue—their pillars of silver on bases of brass, rising amidst vines and fruit trees—even allowing for all the exaggerations of the poet—dazzle the imagination with much of the gaudiness and glitter of an oriental city. At this period Athens receives from Homer the epithet of "broad-streeted"; and it is by no means improbable that the city of the Attic king might have presented to a traveller, in the time of Homer, a more pleasing general appearance than in its age of fame, when, after the Persian devastations, its stately temples rose above narrow and irregular streets, and the jealous effects of democracy forbade to the mansions of individual nobles that striking pre-eminence over the houses of the commonalty which would naturally mark the distinction of wealth and rank in a monarchical, or even an oligarchical, government.

Vitruvius's Principles.

The principles of composition which he would have us ever keep in mind in the formation of a design are six—ordination, disposition, eurithm, symmetry, decor and distribution. Ordination he defines as "the adjustment of the sizes of the several parts to their uses, and to the general scale of the building." Perrault and Newton have quite altered this part of the text of their author, the former confessedly and without authority; whilst Martin, Galiani, Sir H. Wotton and others have been at a loss to comprehend what *ordinatio* meant, though it evidently stands for that principle of the art which teaches us to give to the parts of designs their appropriate size; for instance, to the several apartments sufficient area for the purposes to which they are dedicated, without making them disproportionately large for the rest of the structure; it requires that to doorways, corridors, stairs, &c., sufficient width be given for the number of persons likely to frequent them; to windows size sufficient for the due supply of light; to supports sufficient but not excessive thickness or strength, &c. Disposition he defines as "a convenient collocation of the parts, and a desirable effect in the composition (putting together) of the work with respect to quality." As then ordination proportions their sizes, so disposition arranges them with reference both to their use (*apta collocatio*) and the general effect of the composition. Eurithm, Vitruvius says, is "a slightly appearance and a suitable look in the composing of members (*i.e.* forming them out of their simple elements), and is secured when the members are of a height suitable to their width, and of a breadth proportioned to their length, and, in short, when all things accord to their own proportion." "So symmetry," he adds, "is a proper concord of the members of the work itself, and the accordance of any given one of the several parts to the appearance of the general form." Eurithm then regards the ratios or relations of the dimensions of any single member, and symmetry the relations of one member to another, or of any given dimension of one member to the corresponding dimension of another. Proportion is therefore of two kinds according to Vitruvius, viz. eurithmic and symmetric—a distinction lost sight of by all his annotators. The former exists between the height of a column and its diameter; the latter between the height of the column and the height of the entablature, and also between the diameter of the column and the width of the intercolumn. Eurithmic proportion obtains between the width and height of a door or of a window, symmetric between the door as a whole and the window as a whole, and between the widths and the heights respectively. Decor-consistency or propriety he defines as "a correct aspect of a work composed of parts, approved with reference to precedent or authority, and is threefold, as it relates to statio, custom or nature." The first translated "station," "circumstance," "stanza," "abitazione," "*situation d'un lieu*," "*etat des choses*," "*statuo*," by Newton, Gwilt, Barbaro, Orsini, Martin, Perrault and Galiani respectively is exemplified, when temples to Minerva, Mars, Hercules, &c., are executed in the Doric order as suited to their stern attributes, and shrines to Flora, Venus, &c., in the Corinthian style to accord with the tender and delicate natures of these latter divinities. Conventional propriety, he says, forbids the infringement of usages approved in all ages—for instance, the introduction of triglyphs into any other order but the Doric, or of dentils into this. Distribution, his sixth and last principle, he explains as "an advantageous dispensation of the materials and site, and a careful and rational regard to economy." As a further explication of his meaning, he adds the Greek term *oikonomia* as a translation of distributio, a word more nearly equivalent to "stewardship" than to any other expression in our language. From this we may understand that it is the province of architecture under this aspect to furnish all the requisite parts of the design without lavish expenditure, but in such manner and measure as may be best afforded by the circumstances of the case. These, then, are the principles of architectural composition which Vitruvius lays down. Ordina-

tion, by which the parts are made of a size appropriate to their use; disposition, by which they are placed in convenient and effective collocation; eurhythm, or the due proportion of the parts, each in itself; symmetry, or unity of proportion between all the parts and the whole; propriety, or consistency and distribution or economical provision of all the essential requisites.

Horace Walpole and Strawberry Hill.

It certainly says very little either for Walpole's discrimination or taste, that with such examples as Eton College and Hampton Court just by, to say nothing of numerous others of ancient domestic and collegiate architecture which he must have been acquainted with, he should have patched up his house at Strawberry Hill with the most wretched "Carpenter's Gothic"—not only sheer absurdity as to style, but so thoroughly barbarous and uncouth in itself as almost to proclaim his ignorance, and convince us that he did not at all understand the mere elements and rudiments of the style which he set himself up as a judge of. It is true he endeavoured to avert criticism by affecting to speak disparagingly of his building, and as a mere plaything for his own amusement; but then the same excuse might be pleaded by any one, if not in justification of his taste, of his right to indulge it, however bad. There would be nothing at all inconsistent at least in an ignorant man's saying, "I know what pleases myself, and so that I do but satisfy myself that is all I seek; I do not ask other people to approve of my taste, for it is quite matter of indifference to me whether they do so or not"; but for an *arbitrator elegantiarum* in architecture to hold the same argument is strange indeed. His right to do as he did was most unquestionable, but the puzzling question is how, if he really possessed the taste the world gave him credit for, he came to do as he did in the first instance, and could afterwards endure to look upon the monster of his Frankenstein creation—"To please himself" is no answer, since there lies the puzzle. "To please himself" is merely acknowledging that, as it was a reflection upon, so it was the reflection of Walpole's own taste, when laying aside his superfine critical airs he gave himself up to it without any ceremony. Those who are good judges of taste of a different kind generally take care to please themselves by reserving some of the choicest portions and tit-bits in the dish which they are helping their friends to. Again, it is but a lame excuse for both Horace Walpole and Strawberry Hill, to say that his means for building were limited, and would not allow him to do more; as a structure it might have been equally flimsy or more so, yet might have been made to exhibit correctness of design and characteristic detail—at any rate, to manifest some kind of feeling for art and some real gusto, although in contradiction to all previous examples. Dallaway talks of a person's being able "to contemplate all that is fascinating in Gothic architecture at Strawberry Hill." Can it be an error of the press—a blunder of the printer, who converted into "fascinating" what was intended for "farical"? Let us hope for the credit of criticism that such is the case.

William Smith and Applications of Geology.

At the close of the last century William Smith had made himself much more accurately acquainted with the actual order of superposition of the secondary strata in England than any person then living. He was also one of the first to apply this knowledge to important practical purposes. About the year 1800 his reputation for "draining on new principles" was thoroughly established in the West of England, and on the occasion of numerous landslips taking place near Bath, he was employed to prevent if possible a recurrence of this mischief, which he effected by tunnelling into the hill on which the land was slipping and intercepting the springs, and then providing a direct and convenient channel by which the water could be discharged. In the year 1811 Smith was again employed to report on a subject of practical science connected with the drainage of strata. About that time numerous canals were being cut in different parts of the West of England, and these, crossing the oolitic hills, were found to be particularly liable to accidents of leakage, being cut through open jointed, and sometimes cavernous rocks, alternating with water-tight clays. In the passage across the former rocks, and more especially when the summit level of the canal occurs in them, the water escapes almost as fast as it enters, and all the skill of the engineer in puddling and making an artificial bed is sometimes exerted in vain, and cannot prevent great and ruinous loss. But the existence of open joints and caverns is by no means the only nor indeed the greatest source of injury, for innumerable small faults or slides traverse the country and confuse the natural direction of the springs, rendering them short in their courses and uncertain and temporary in their flow, weakening by their irregular pressure every defence that may be opposed to them and causing leaks, which let through a portion of the water contained in that level of the canal. The general remedy for all these evils was understood by Smith, and proposed by him for adoption. It is the entire interception of all

the springs which rise from a level above the canal and pass below it through natural fissures and cavities. This is a process requiring great skill and extensive experience; some of the springs, for instance, which it is most important to intercept come not to the surface at all in the ground above the canal, but flowing naturally below the surface through shaken or faulty ground, or along masses of displaced rock which extend in long ribs from the brows down into the vale, emerge or attempt to emerge in the banks of the canal; these no ordinary surface-draining will reach, and none but a draining engineer well versed in the knowledge of strata can successfully cope with such mysterious enemies. But Smith, confident in his great experience, not only proposed, by a general system of subterranean excavation to intercept all these springs, and destroy their power to injure the canal, but further to regulate and equalise their discharge, so as to render them a positive benefit. This he would have accomplished by penning up the water in particular natural areas or pounds which really exist between lines of fault in most districts, or between certain ridges of clay ("horses") which interrupt the continuity of the rock, and divide the subterranean water-fields into limited districts, separately manageable for the advantage of man by the skilful adaptation of science.

The Loggia of the Vatican.

Although the paintings in the Loggia of the Vatican pass under the name of Raphael, it is not pretended that they are the work of his hand, nor even his designs. He was indeed the originator and director of the whole, and the character and influence of his taste is visibly stamped in every part. But his coadjutors in the work were artists whose names are inferior to none in the Roman school but his own, such as Giulio Romano, Perino del Vaga, Benvenuto Tisi and others, who were occupied not only in the execution but in the invention of the details. Francesco Penni and Andrea da Salerno are particularly noticed as being employed for the figures, Giovanni da Udine for the fruits and flowers and Polydore Caravaggio for the reliefs. Quatremère de Quincy is of opinion that the sculptures of the Parthenon were produced by similar means, Phidias there performing exactly the same part as Raphael in the Vatican, and it is indisputable that the combination of unity of design with variety of detail which characterises Gothic architecture could have been produced only by the same system, and by employing the minds as well as the hands of those by whom the decorations were executed. When we see perfection attained in three distinct styles of art, in three distant ages, by means precisely similar, it is not too much to assume that these means are probably the right ones. The Loggia of Raphael form an arcade in thirteen compartments. The arches are open, or at least were so originally, towards the court, of which the Loggia forms one side. The opposite side is a wall pierced with windows, one in each arch, giving light to the suite of rooms which contains the great frescos of the painter. The ceiling of each compartment forms a square cove, on the sides of which are the panels containing the series of scriptural paintings, the engravings from which are known as Raphael's Bible. These are his own designs, and some are known to have been touched with his hand. Both the lateral and cross arches are supported by pilasters about 16 feet high, panelled and decorated with coloured arabesque on a white ground. Each pilaster on the wall side is flanked by a half pilaster, in which the arabesque is carried through on a smaller scale of composition. Notwithstanding the great variety in the composition and details of these works, we shall find a general unity of design prevailing throughout, with the exception of the last five of the series. Whatever form the composition may take, it is rendered subservient to the introduction of four medallions or tablets, relieved from the background in stucco, of contrasted shapes, one like an antique shield, the next circular, the third rectangular and the fourth in the form known as the *vesica piscis*. These medallions occupy the upper part of the pilaster, to the extent of about one-third of the whole panel, while the lower part, to the height of the dado, or somewhat higher, is generally filled in such a manner as to afford a weight of colour, sufficient to support itself by the side of that member of the architecture and the members introduced into its panels, following in this respect the practice of the ancients. These medallions might appear to violate the due balance of the arabesques, if they were identified with them; but the composition is rescued from that fault by the separate character given to the decoration of the medallions, and by their being detached and hung, as it were, independently upon the background. In the general arrangement of the whole, these medallions perform a very important part, connecting the pilasters with the panelled stuccos adjoining, both by their relief and by means of an accordant style of decoration and a similarity in the subjects represented upon them, neither of which could have been well embodied in the arabesque itself. But it must be admitted that these compositions, considered separately, are somewhat unequal.

NOTES AND COMMENTS.

THE inquiry into the working of the Technical Education Act, which Lord NORTON proposes, cannot be considered as premature. Unless we are mistaken, it will not take many days to discover how useless is much of the expenditure. A slight revelation of the weakness of the system is afforded by the official confession that many of the casts purchased as models are unsatisfactory. It is not necessary to say that the Technical Education Board proposed to find a remedy by despatching a commissioner in state to visit the Continent. For the last forty years, whenever a simple difficulty arose or a defect was discovered, the occasion was seized to arrange a continental tour for some official connected with the Science and Art Department or its predecessor. By this time there ought to be enough reports available to show the number of panes of glass in every technical school in Europe and the cost of scrubbing the floors. In the present case Professor MIDDLETON, who had started on a purchasing tour for South Kensington, voluntarily offered to look after the casts without extra charge. He has been authorised to expend 500*l.* on them. When it is remembered how much money the Science and Art Department has managed to disburse, it is remarkable that the country has not yet acquired a sufficient number of objects which could be reproduced as casts for the benefit of the humble students who join technical classes. There is no doubt the South Kensington Museum possesses many valuable things, but, whenever a test is applied, it is found that every section is no less deficient in what is required than that of casts for elementary purposes, and it becomes necessary to appeal to foreign help. In the fifties there was some excuse for subjection to the continental teachers, but now it has become humiliating.

THE Earl of MAYO has prepared a scheme for the formation of an Arts and Crafts Society for Ireland. It is proposed, in order to carry out the objects, to hold an exhibition of Irish arts and crafts in Dublin during the autumn of 1895. For that purpose a council of a thoroughly representative character will be formed to take charge of the arrangements. A guarantee fund of at least 1,500*l.* is to be raised. A committee of selection will also be constituted to decide, when exhibits are sent in, whether they are worthy in their different classes of a place in the Arts and Crafts Exhibition of Ireland. All firms, societies, tradesmen, artists, designers, and individuals who are interested in the various crafts will be invited to send exhibits. It is intended that at all exhibitions held under the auspices and direction of the Society, the name of the artist, designer, workman, as well as the name of the firm or tradesman employing them, shall be clearly set forth on all exhibits. Irish artists and craftsmen resident in Great Britain may send exhibits. Originality of design and form is desired in the objects sent; therefore, no absolute copy of old or modern work can be accepted. The first exhibition is to consist of examples of architectural designs, bell-founding, bookbinding, cabinet makers' work, cast-iron, embossed leather, embroidery, engraving, lithography and book illustration, gesso, stucco and sgraffito work, glass, gold and silversmiths' work, hammered ironwork, lacemaking, lapidary work, poplin making, porcelain and pottery, printing, repoussé work, seal-cutting in stone, brass, and steel, stone and marble carving, terra-cotta, wall-paper designs and wood-carving. We hope the Arts and Crafts Exhibition will be more fortunate than the last exhibition of Irish industry at Kensington. As the sum to be raised for six months' expenses is most modest, being only 1,500*l.*, there cannot be much of a display, but that may not be without advantage.

THE vandalism of one of the guardians of the treasures of the Cathedral of Sens, by which the chasuble of St. Thomas à Becket has been mutilated to gratify a woman, is likely to make the French people insist that the national property shall be entrusted to more careful hands. That the vestments are genuine is generally believed by archaeologists. The Archbishop of CANTERBURY fled to Sens to consult with the Pope, who was also a fugitive in that city, and afterwards remained there for about six years. It is not unlikely that he would leave vestments

behind him, which were probably borrowed from the Archbishop of SENS. A part of the chasuble was cut out with an absence of secrecy that suggests how little value was attached to the antique by the clergy. If inquiry were made it is possible many other acts of vandalism would be revealed. It would be better to allow antique remains to rest in places where their interest is enhanced by associations; but if the authorities of a cathedral cannot restrain their hands from vandalism, it would be wiser to remove temptations from them, or to insist that an officer belonging to one of the museums should have the charge of all articles that can be mutilated.

ARCHÆOLOGISTS have reason to be grateful to PROSPER MÉRIMÉE for his efforts as founder and director of the department which has charge of ancient buildings in France, although he inspired operations of renewal which were not always advantageous. As a writer of short stories like "Colomba" he is almost without equal, while his historical and other books would by themselves gain reputation for another writer. His countrymen have not, however, adopted the usual course to uphold MÉRIMÉE'S reputation. There is no statue of him in a public place, and his name does not appear on a plaque as a title for a street in Paris. The explanation is that MÉRIMÉE was attached to the imperial senate. Many other men who appeared to be bound to the late court were forgiven, for they appeared to be only playing parts. But MÉRIMÉE, who had known the Empress from infancy, endeavoured to watch over her interests, and his fidelity was a crime which no literary ability could condone. An admirer who is the owner of an *impasse* has decided to compensate for the neglect of the Municipal Council by changing the name it bore, *Impasse des Belles-Feuilles*, into *Rue Mérimée*. Let us hope the tenants will not resent his efforts and compel him to reduce the rents.

IT is remarkable how persistent lawyers are in their endeavours to make the sheets of the Ordnance Survey be accepted as evidence in the law courts. The Scottish courts witnessed one of those efforts, but it was defeated on Monday last. The action was between two proprietors over a weir on the Tay. The plaintiff's case was that a weir which used to extend across a part of the river had been extended gradually by the defendant until it reached from bank to bank, causing damage to a salmon fishery, for which 200*l.* was claimed. The defendant maintained that the weir from time immemorial was constructed across the river and that his operations consisted solely in repairs to the foundations. A great many witnesses gave evidence for both parties. The plaintiff was apparently a stranger, and seeing on the Ordnance Survey of 1864 that the weir was represented as occupying no more than about two-thirds of the waterway, he concluded that the extension must be the work of a recent period, and the Ordnance map was relied on in support of his contention. The judge, however, laid down that in the absence of any oral evidence from the persons who made the survey, or of the circumstances in which it was made, the map could not be accepted as evidence. It would, said his lordship, be manifestly most unfair without knowing a great deal more than they did to attach any importance to the map, because it was quite possible that the survey might have been made at the time when one end of the dyke was temporarily washed away, or when the river was so high as not to show it. But if the map had been proved in the proper way there would still have been a difficulty in reconciling it with the rest of the plaintiff's evidence, for most of his witnesses said that the free space between the end of the weir and the bank was only about one half the breadth shown on the map. Judgment was therefore given in favour of the defendant with costs. A case of the kind must compel people to believe that the Ordnance maps on a large scale are of little use. They cannot be trusted as exact representations of detail. The surveying of that part of the river which was the scene of the dispute must have cost the country a good many pounds, and then there was the expense of engraving. Probably the only copy of the map which was purchased since the publication was the plaintiff's, and by misleading him he has become involved in a very costly lawsuit.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Architectural Association was held on Friday evening, Mr. E. W. Mountford, president, in the chair. It was announced that the annual soirée would be held on the evening of the 4th prox.

Mr. W. HOWARD SETH-SMITH read a paper on the

Bases of a Successful Architectural Practice in the Twentieth Century.

He said:—My subject is a well-worn—shall we say a threadbare one? For this I crave your pardon, but still hope that its perennial and vast importance, and perhaps a few new points of view which I shall take this evening, may invest it with some life, interest and usefulness, and may promote discussion.

Architecture requires four qualities in its creator:—1. Common sense. 2. Thoughtfulness. 3. A cultured sense of beauty. 4. Skill in expressing this by drawing.

Modern engineering is the product of common sense, thought, and skill in drawing, without the sense of beauty, and is therefore not architecture, in spite of Mr. Beresford Pite. The public have plenty of common sense, and engineering is accordingly the most popular profession. The public is in sympathy with, where it does not create, the characteristic conditions and tendencies of the age, and hence the inexpediency of the devotion to antiquated ideas which has largely contributed to alienate the public from our profession.

If we would be successful architects we must above all things adapt ourselves to these characteristic conditions and tendencies of our own day. What are they? Firstly, the worship of mind rather than of money or of art. It is pre-eminently the age of science, and woe be to the architect who, in the exclusive pursuit of that which as artists we all love best and would fain devote our whole time to, overlooks this fact.

The result of this worship of mind is an immensely increased demand for education, especially in professional men, with the inevitable result that those who intend to excel (I am not referring to men of special natural endowments; we may safely leave genius to take care of itself: I am arguing for men of average ability, this class including the vast majority of us) must be prepared to prolong their infancy in proportion to their determination to succeed. I use the word "education," of course, in its wide sense of expansion of the mind in many directions, and in as great a degree as is practicable. None will, I think, dispute this tendency. The formation of all professional societies is a concession to this condition of things.

The outcome of this tendency is the demand for some means (other than that of experience acquired by practice) of ascertaining the possession of superior culture as entitling to its confidence those who profess to advise the public. The only means yet devised is public examination of our students and due registration of the result. The decision in favour of examinations, in spite of the drawbacks of the system, is as general as is the opinion that the early training for all professions should be as wide and general as possible, the specialist study thus being better grounded and pursued more intelligently and safely. The election of experienced practitioners to membership of societies may have sufficed in the past as a rough-and-ready test of qualification, but much more is demanded nowadays. This is clearly seen in the establishment on all hands by professional bodies of examinations as a condition of membership.

A second phenomenon of our times is the reduction of large fortunes and large incomes, the distribution of money, and the consequent probability of our patrons consisting in the future more largely of the non-cultured and non-artistic class—a class which affects art, but knows little or nothing about it, but in my experience is willing to be advised and led.

A third condition is the distribution of means of culture by high-class schools, university extension courses, good provincial art libraries, technical schools, cheap travelling, &c. The provincially trained architect may by these means be in the future as good a man in art and perhaps in respect to general experience as his metropolitan brother, and will be consequently more largely employed in important undertakings.

The teaching of these considerations is clearly that the public first of all requires us as a profession to be thoroughly qualified all round—skilled planners, masters of the various principles governing the building trades, critics and directors

of all departments of building, experts in building law, &c.; they further teach us that we must devise some means of letting the public know that we are so qualified. I know many of my artistic critics will cry out I am degrading our art by such a statement, but I make it emphatically, and I make it in the interest of art, as I shall endeavour to prove.

I would ask all those who appear to be in opposition to this view to answer candidly the following questions:—

1. In spite of some little improvement, does the British public love, and is it able or willing to pay reasonably for art in our work? (I am quite aware that good architecture need not be costly—on the contrary, it is generally less costly than bad, owing to its detestation of display and love of invention—but it would be absurd to argue that it costs no more than the purely utilitarian.) Addressing the Liverpool Art Congress only about six years ago, Sir Frederick Leighton, as you may recollect, said:—"Our countrymen have no adequate perception of the place of art as an element of national greatness; they do not count its achievements among the sources of their national pride; they do not appreciate its vital importance in the present day to certain branches of national prosperity; while what is excellent receives from them honour and recognition, what is ignoble and hideous is not detested by them—is indeed accepted and borne with a dull acquiescence; the æsthetic consciousness is not with a living force impelling them towards the beautiful, and rebelling against the unsightly."

2. I would ask, Do you profess to act as the censor and dictator in the complex technical and practical matters in connection with your buildings? If not, you will not at any rate dispute that your clients remunerate you on this understanding.

Is not the reason of our employment most frequently the utilitarian benefit our skill in planning and our knowledge of building business will insure? And is not the fact that an architect is so often not employed to advise in considerable building operations due to the fear of his artistic ideas enhancing the cost, or perhaps to the suspicion (alas! in so many cases the reasonable suspicion) that his training in practical building is not equal to that of the builder's?

The supreme problem before our profession is, therefore, how to establish public confidence in our fitness to be the guardians of our clients' interests. This cannot be done by appealing to an instinct for art which does not exist, but it can and will result from the establishment of a conviction that we have enjoyed a lengthy training in, and therefore possess a superior knowledge of, those departments of our work which the public do appreciate and must and will have. It is folly to reckon without your host, as many among us are endeavouring to induce our students to do, forgetting in their laudable enthusiasm (which the young architect is only too ready to catch, and, through want of experience, to magnify to a perilous degree) for artistic design that they happen to have been the lucky but small minority who are employed by the highly cultivated and wealthy few, while those they address will have in the vast majority of cases to struggle with the difficulties and disappointments of a more ordinary practice, a very large proportion of which will consist of utilitarian work.

In connection with the incidental difficulties and disappointments all architects meet with, I must relate an anecdote in connection with the legal profession which would apply with equal point to our own work. (As a hint to students on the subject of charges its application may be more questionable.) Some of you are doubtless acquainted with the Scotch term "fash."

Sir Edward Watkin was going through a lawyer's bill of costs, and coming upon the item "to fash, 30/," was puzzled. Sir Edward, who knows his way about pretty well, felt completely floored. He either sent for or called upon the solicitor, who happened to be a Scotchman, and asked what the charge 30/ for "fash" meant. "What is 'fash'?" The lawyer replied, "Pens, ink, papers, things you can't carry in your head and general mental anxiety." What a long bill for "fash" we architects might present.

The tendency of the agitation which would place architecture "on the same footing as sculpture and painting" will, if persisted in, throw more and more of our work into the hands of firms of builders who ostentatiously undertake to do the architectural designing as well as the contracting, and thus to lead up to a system which prevails in parts of the Continent, in which the public employ the builder and the builder the architect.

Supposing we can attain our object as a profession and win a much more general respect and confidence in our work, will not the result be immensely more beneficial to the progress of art than any improvement we can hope to attain by parading a qualification which is not yet appreciated by the majority of our employers?

Much indeed is now being done to repair the damage we have suffered in the past, and still suffer, from our haphazard training of young architects. The curriculum of our A. A. is, to my mind, by far the most useful and the most promising of

these efforts, for the two reasons, that it encourages and supplements the all-important pupilage system, and that it is directed not by theoretical educationalists but by a body of architects who ought to be able to judge as to the subjects most required and the relative prominence to be given to them.

I shall make no apology for referring more at length to the great controversial subject of examinations as a test of training. Apart from the enormous incentive they provide to systematic study, the public demand them as the only practicable method of enabling them to ascertain whether a professional man has had a proper training, and I have yet to see urged any reason sufficient to warrant the exclusion of architecture from compliance with this demand. The most plausible objection hitherto urged appears to be that engineers have never found it necessary to institute a compulsory test, but the very essence of an engineer's calling obliges him to have a thorough technical and practical training, whereas the essence of ours constitutes a temptation to neglect those interests to protect which our clients generally employ us.

I say emphatically that in the interests of art we ought to be thankful to the Institute for its establishment of a system of examinations. To preserve, improve and make them general should be our aim. Some of us may not have realised that their existence is threatened, but to my mind last year's decision of the Institute in favour of continuing an art examination as alone qualifying for fellowship of the Institute appeared to be a heavy blow struck at the whole system of the progressive examinations. That decision must frequently involve injustice to the Associates if the obligatory qualification for associateship by examination is still to be insisted on. Men who fail to pass the general examinations compulsorily qualifying for associateship necessitating four years' hard work, can now attain the higher distinction of Fellow by the mere fact of so many years' practice and in the production of some building of more or less architectural merit. That this resolution was urged and passed by the exertions of the majority of the more artistic men in the Institute I admit, but one cannot shut one's eyes to the logic of the decision. I believe it must result either in electing the Fellows only from the Associate class; in the election of Associates on much the same test as the Fellows; or perhaps in conferring the title of Fellow in future only upon such architects as have specially distinguished themselves in the province of art.

As to the improvement of the examinations, this is neither the place nor the occasion to go critically into such a question, even were I qualified to do so, and I will content myself with stating that the British public believe in a practical rather than in a theoretical training, that the cramming system must be by all means discredited and the weakest men must be encouraged. Also my conviction that the system of honorary examiners can never work satisfactorily, though I appreciate as fully as anyone the great services hitherto rendered by these gentlemen.

May I venture any further and say a word about registration? If so, I would ask, what is the Institute of Architects but a society whose object is the registration of qualified men? Would that its principles of obligatory tests might be applied to the profession at large. Of course this can only be done (oh! terrible word) by an Act of Parliament. I believe that such a measure might be drafted by the Institute as would obviate the main objections, whether just or not, urged against the present Bill. Such a measure promoted by the Institute would become law directly our legislators found time to deal with practical politics; the result would be to exclude untrained men from calling themselves architects, and so under false pretences obtaining work which only a highly trained person is capable of performing, and would put a stop to a state of things which has indubitably brought our craft into disrepute. And why should we not anticipate that as great an improvement would eventuate in the quality of the profession generally as has taken place in the ranks of the Institute as a result of its examinations, and that with the growing popularity of the profession art would begin to flourish and improve?

Many here will remember what the chairman of the London County Council said during the discussion on Mr. Collard's paper. Mr. Hutton said that, "In his judgment, as a layman, he considered that the architectural profession suffered greatly from being an open profession. He might be wrong, and if so they would correct him. There was no obligation for a particular course of study, and therefore their profession might be called an open one. He thought that was a grave disadvantage, because he regarded, as he had said, the responsibility of architects as very great." Men generally believe in a great and well-organised profession, and expect great things from it, but they suspect an ill-trained and dislocated class such as the profession of architecture has hitherto been. It may also be asserted that a well-organised profession tends to produce great men.

I am anxious that what I have sought to urge in this paper should not be misunderstood to discount in the smallest degree the art qualification. This must be in any system of training the main thing, but my point is that the man who commends

himself to his *clientèle* as thoroughly qualified to guard those more practical interests which are paramount in the public mind, will, if he be also a qualified artist, have many more opportunities of producing architectural beauties than the man who, by parading his contempt for much of the work which properly appertains to building, creates distrust and even aversion in the mind which cares not for his art, but which can generally be led to understand something about it, and thus ultimately to admire it.

We London men are so apt, too, to forget country architects, who, were they not men of very general practice, could not possibly exist; and is our training and testing to be solely for the benefit of our great cities?

Our wisdom will be best shown in endeavouring to meet our clients' wishes, even when they may appear to us eccentric, prejudiced, or ignorant. Nay, may we not rather regard this as among the ethics of our calling, and as important as honestly estimating and fearlessly reporting the cost of projected work and many similar somewhat unpalatable duties? A conscientious and a thoughtful attempt to do this will generally result in unexpectedly original and beautiful features.

A practical suggestion was recently made by the *St. James's Gazette*, which I believe would result in good to architecture, and the *Daily Graphic*, noticing the remark, observed:—"Some time ago we advocated the desirability of the names of architects being placed in some prominent position on the buildings for which they are responsible."

The *St. James's Gazette* has now taken this matter up. It says, speaking of a modern building of great excellence, "While the frontage is placarded with advertisements concerning what we do not want to know, namely, who is the builder, the electric-light fitter, &c., not even a tiny tablet records the name of the artist in whom the public is most interested. If all our buildings were properly labelled, it would be a distinct gain from an educational point of view." If all architects felt that the erection of a work inevitably exposed them either to public opprobrium or esteem they would generally be much more careful of their reputation than they are at present.

There are many other essentials to successful individual practice which, when I decided early in the session to speak on this subject, I had in my mind to refer to; many of these have, however, been so ably stated by readers of other papers, particularly by the President, Mr. Beresford Pite and Mr. Collard, that I felt obliged to confine myself to the broader politics of the profession. I do not regret that circumstances have led me in this direction, as it has always appeared to me that all other professional questions sink into the background as compared to that of how best to satisfy the wants and to inspire the confidence of those who desire our advice, and if my reasons for adopting as the best means to that end the three main principles laid down in this paper, namely, (a) a prolonged systematic course of study, (b) examinations as a test and public proof of knowledge, and (c) the closing of the profession against unqualified men—if these reasons should appeal to your minds as sufficiently strong to warrant the adherence to these principles of those who are destined, as you are, to control the course of professional affairs in the near future, I shall feel that a distinct advance has been made towards the elevation of our art to its proper place in the affections of the people of this country.

Professor KERR, who spoke at considerable length, alluded to the benefit of students hearing the results of the experience of their seniors—men who had borne the heat and burden of the day. Though they might not predict what would be at the end of the twentieth century, they might speculate on what would be the character of the business in the first quarter of that century. Mr. Kerr referred to the paucity of architects when Sir William Tite was president of the Institute of Architects, and as that state of things was altered, students might rightly try to judge what their work in the future would be. Architecture consisted of three parts—art, science and practice, or business. Could they foresee what students would have to look forward to and to prepare for? He thought they could. In six years—it was but a short time—they would have the twentieth century upon them. First, in regard of practice or business. The English people gave a business-like consideration to everything they did; there was no sentimentalism; they were not like Frenchmen, who went to war for an idea. Englishmen employed an architect ninety-nine out of a hundred times to see them safely through a building transaction, no light task, and men who were distinguished artists among architects would plainly say their greatest difficulty was to carry through a building transaction creditably to all and satisfactorily to the client. Young architects must study business first and leave science and art till later. He must devote himself to the class of work in the office that seemed to be below him, and keep his ear open for all that regarded the transaction of business. As to science, he should devote himself to mathematics and calculations. Tables with calculations of scantling of timber, &c., might be used to save time, but the young architect should be able to calculate them himself. He should not forget to study chemistry, geology and the superficialities of

such sciences as he would have to deal with. In the twentieth century the public would not study whether an architect belonged to the Institute of Architects, but whether he were a practical man. Art was always a difficult question. It might be discussed for ages to come, and never be discussed too much. The English were not by gift an artistic people, unlike the Latin races, especially the French. If he ventured on a suggestion, he would say that the turn the world was taking would bring about a change in the artistic development of Europe at large, which would bring the Teutonic race to the front. If that happened the young architect must be prepared for it, and to be more artistic than at present in the way of common-sense art, that the public would look for. England, he thought, was steadily advancing in this respect. The fault of our school of art was lack of dignity. The French, the princes of architectural art in the present times, never lacked dignity. We were emerging from the dreary state of things belonging to the Gothic revival to a brighter state of things. Matters were on the move, and had advanced in the right direction. The popular style of architecture of the present day was a stepping-stone to something better. The young architect should not study *bric-à-brac*, but all examples of architecture that were really grand. England would always appreciate grandeur, repose, dignity, &c. They were embarked in a profession in which they could not become successful practitioners except by great study, diligence, perseverance, and dependence on their own intelligence.

MR. ALBERT GOODMAN proposed a vote of thanks to Mr. Seth-Smith for his paper. He thought the English would never be an artistic people, and financial questions hampered architecture.

MR. E. DORAN WEBB, following up some remarks of the last speaker, considered that an architect had better give up a client unless he could have his way and put up a building which would not do him credit, but prevent other clients employing him.

MR. T. BLASHILL said that young men going in for architecture must have a real liking for it and interest in it, then there would be no drudgery. Burke, if he remembered right, said about taste, that the shortcomings were not from want of taste, but from want of knowledge. A youth entering an office must keep himself in the closest possible touch with business. Art, science and business—he had never attached much meaning to those terms. Whatever branch of his profession the young man followed, that was his art; in other words, systematised knowledge, an intensely close and accurate knowledge of all his business; and then whatever they did in any branch of the profession was art.

MR. PAUL WATERHOUSE observed that newspapers seldom mentioned an architect's name. They gave full descriptions of buildings, and the names of every one, even the builders, but not the name of the architect.

MR. BEALE, referring to the bases of architecture described in the paper, more particularly the one dealing with the necessity of more general knowledge, described the nineteenth century as an age of specialists, and expressed his pleasure that Mr. Seth-Smith had put in a plea for the all-round man.

MR. W. RIMMINGTON expressed his opinion that the modern buildings now rising in England pointed to a strong artistic revival here, which he had failed to see abroad, and had not found in Italy, France or Germany; or, if he made an exception, he had only found it in Germany.

MR. C. H. BRODIE, in a characteristic speech of about half a minute, condemned the idea that architects should build for clients on the plan of carrying out their own views instead of their client's requirements or else refusing the work. For instance, if a client only wanted to spend 200*l.*, and an architect saw the work carried out for him for 150*l.*, that architect would succeed. That, he thought, was one base of architecture that held good in every century.

MR. F. T. W. GOLDSMITH, hon. sec., alluded to Mr. Seth-Smith being still in favour of registration, though perhaps in a modified or amended form. Mr. Goldsmith said that architects, however critical among themselves, should not go needlessly out of the way to run down each other in public. Architects should cultivate something of the social instinct that seemed to pervade other professions.

THE PRESIDENT gave his opinion that "a good time was coming." As to the training of students, London students had book knowledge and provincial students practical knowledge. Examinations, he thought, tended to keep a man in the background. A student should devote the utmost possible attention to design, and the rest would come from experience. He did not think it was necessary for a student to study minor details. Neither did he agree with Professor Kerr in his remarks on the Gothic revival. That revival had done much good. It had left its mark on our architecture which, with the Classic revival, would produce great results in the future English style. The President then put the vote to the meeting and it was carried by acclamation.

MR. SETH-SMITH replied and the meeting adjourned.

THE GREAT CLOCK OF ROUEN.

THE great clock, the pride of the people of Rouen, writes M. Reverchon, cannot perhaps claim to be the most ancient in France; that of the Palais de Justice and the great clock of Caen may justly claim to dispute with it the honour of antiquity; but it is certainly true that none other can compete with it in perfection of construction. A clock which has practically been going regularly and striking the hours and quarters for over five hundred years, may fairly be regarded as a valuable piece of mechanism, especially in this epoch when a pendulum which has been going fifty years is considered a marvel. The great clock of Rouen stands unrivalled in this respect.

Finished in September, 1389, by Jehan de Féalins, it has been running without interruption from that day to this, requiring nothing except cleaning and a few trifling repairs of its accessory parts. It was certainly not with this clock that the famous proverb originated, "This is the palace clock, which goes when it pleases." On the contrary, the great clock of Rouen had so accustomed the citizens to look upon its exactitude as a matter of course, that when, in 1572, the breaking of a wire prevented its sounding five o'clock one morning, the population was in a state of consternation. The magistrates summoned the custodian, Guillaume Petit, and remonstrated gravely with him.

¶ This unparalleled course from century to century is all the more remarkable from the fact that until 1712 the great clock had no pendulum. For 325 years it had no other regulator than a "foliot," an apparatus of which the majority of modern clockmakers hardly know the name. It consisted of a vertical rod suspended by a cord supporting a transverse beam, the arms of which terminate in a serrated edge; on their serrations are movable weights called regulators, which by change of position augment or diminish the force of inertia of the machinery. To the rod are attached two spurs which receive alternately the impulsion of the teeth of the balance wheel operated directly by the clockwork. The special characteristic of this regulator is the absence of that which constitutes the essential feature of the pendulum, namely, a natural point of inertia. It might be said of it that then it was a clock capable of regulating its regulator with a nicety determined by the degree of the precision of the cutting of the teeth of its balance-wheel.

The case of the clock occupies a space of 6 feet 8 inches long, 5 feet 4 inches broad, and 5 feet 10 inches high. When one thinks of the size and of the labour of construction by hand of the great wheels of this admirable piece of mechanism, it may easily be inferred that the maker, Jehan de Féalins, had ample time to eat up all the little sum he was paid.

The pendulum was introduced in clockwork in 1659; but so well were the good people of Rouen satisfied with the time-keeping qualities of their famous old clock, and such was their veneration for this masterpiece of mechanism, that fifty-three years were allowed to pass before the pendulum was substituted for the "foliot." Equipped with this new apparatus, it has continued to this day to strike the hours and chime the quarters.

In 1892 the Commission of Historical Monuments decided on the restoration of the dial and of the two accessory movements of the great clock, which show the days of the week and the phases of the moon.

THE LATE W. HAYWOOD.

THE late engineer to the Commissioners of Sewers, Colonel William Haywood, did not long enjoy his retirement from the active duties of his office. He died on the 13th inst. in his seventy-third year. Mr. Haywood was appointed engineer to the Commission in 1846, having been previously assistant engineer, and during his forty-eight years' tenure of office he rendered many distinguished services to London. In 1851, with the late Frank Forster, who was Robert Stephenson's lieutenant at the Britannia Bridge, he prepared a scheme for diverting the sewage from the northern side of the Thames. In 1854 Sir Joseph Bazalgette and he extended the scheme, and it was eventually carried out by the Metropolitan Board of Works. In 1856 he designed and laid out the City of London Cemetery at Ilford. From 1863 to 1870 Colonel Haywood carried out that gigantic work, the Holborn Viaduct, which cost from the Coal Dues nearly four millions of money, and which was opened by Her Majesty in person on November 6, 1869. In 1879 he laid down a complete system of fire hydrants for the City, where it was first established. In 1883 he designed and erected a crematorium for burning street refuse. Earlier still, he suggested the site of the new Tower Bridge, and it is stated that during his period of service he carried out improvements in something like half the streets and places of the City at an expenditure of some millions. Among these may be mentioned the construction of Queen Victoria Street and the widening of Ludgate Hill. He was the first to lay down asphalt pavements in the carriage-ways of London.

CATHEDRAL OF BITONTO.

THE Italian Government have acted wisely in subsidising the production of photographs of buildings in districts which are outside the courses usually followed by strangers. Apulia is a region which has had a remarkable history, and evidence of the variety of rulers is to be found in the churches. The cathedral of Bari is one of the best-known examples. No less interesting is the priory of St. Nicholas, on which the Norman conquerors expended large sums of money. Bitonto, which is about ten miles from Bari, resembles in detail the church of St. Nicholas. The west door is no less rich, and figures of animals are introduced

as architectural elements. The ornament in relief nearest the door has a northern character, weird animals being employed largely. The treatment appears more remarkable from the contrast with the ornament near it, which might have been taken from a Roman building. In the lunette the figures are also of a northern type. In the upper part the subject appears to be "CHRIST amidst Saints," in the lower part the Annunciation, Visitation, Adoration of the Wise Men and Presentation in the Temple are combined. Several other photographs of the cathedral are published by Signor MOSCONI, of Rome, in his invaluable collection, which is illustrative of Italian architecture.

PRINCIPAL DOORWAY CATHEDRAL OF BITONTO APULIA

THE FREE CLASSIC REVIVAL OF 1870-80.*

I HAVE taken as the title of this lecture "Queen Anne or Free Classic Architecture." In its preparation I have kept in mind the fact that in the study of any one period of architectural history there is much that antedates that period that must be studied to clearly understand the influences that contributed to the development of the style under consideration, and which stamped an impress upon its art features and constructive forms. These influences cannot be ignored, and although in the preceding lectures you have been led onward through the various types of Pagan, Early Christian, Mediæval and Continental Renaissance, it has been with reference to their bearing upon each other and not with the view of analysing their connection with the architecture of the early part of the eighteenth century.

It is impossible in a single lecture to go over all the previous ground and investigate in an exhaustive manner the influences working upon English architecture during the two centuries preceding the reign of Queen Anne, but some slight attention must be given thereto, if only to serve as a connecting link between the older and newer styles, and to define their dependence upon each other. You will, I trust, pardon me if I briefly refer to earlier works of the great English architects, and urge you to study carefully the state of English society at the beginning of the eighteenth century, together with the material resources and limitations under which they were compelled to work. I propose also to add some notes upon the influence of the Queen Anne school upon modern work, with particular reference to the Free Classic revival of 1870.

Of all the recognised styles of architecture, the position of Queen Anne, or so-called Free Classic, is perhaps the most difficult to determine. The nomenclature will assist us but little in investigating its art history and constructive laws—the term "Queen Anne" being as much too narrow as "Free Classic" is too broad. If we ask professors of architecture and the more learned practitioners of the art for information on the subject, we meet with vague and unsatisfactory replies. Younger and more enthusiastic architects, and the devotees of spinning-wheels, blue India china, teapots and green crown glass would, during the early days of the revival, have unhesitatingly answered that Queen Anne was "high art," forgetting that art had reached its lowest ebb in England when William and Mary ascended the throne made vacant by the Stuarts.

With such diversity of sentiment and reasoning how shall we elucidate the truth? When did Queen Anne architecture originate, who were its great masters, where is its literature, what influence did it exert upon the life and manners of its early years, what causes led to its decline and to what source may we trace its sudden and aggressive renaissance?

To the student of architecture who looks beneath the surface of fashionable art culture the Queen Anne and Georgian period seems almost like a mirage, where he sees dimly reflected vistas of city streets, lined with tall houses built of red brick, tiled roofs, long and narrow sash windows painted white, and outside shutters painted green. The academies tell us that early Queen Anne was a feeble application of Palladian rules, designed for palatial works in marble to smaller edifices built of brick, and that late Queen Anne was simply a craze that has now almost run its course and is gradually sinking into oblivion as did its prototype. This lack of definite historical data is the more remarkable when we consider that Queen Anne is but of yesterday, while the records of building in general are full and copious in outline and detail.

We can follow the gradual development of styles and systems of construction and their transition into other and later styles, from the earlier hut of the Aryan Hom down through the Egyptian, Syrian, Grecian, Roman and Byzantine, through the wondrous science of the Middle Ages to the wealth and luxury of Continental Renaissance. England gradually remodelled her feudal castles into the noble and picturesque manor-houses of the Tudor kings, and the architects of Elizabeth's reign carried this somewhat fanciful but at the same time dignified type of architecture to its utmost development.

All this will be clearly and logically explained by the academies. They will further add that after the accession of the Stuarts the building art gradually declined, with only a few flashes of brilliant light in the works of Inigo Jones and Wren. The Commonwealth was prudish in art as in manners, while the Restoration was a reign of revel and wild license. Queen Anne's social world, stiff, starched and formal, left its impress upon the buildings of its day, which were mostly of a domestic character. The art of the Georgian reigns followed—more refined in sentiment, delicate but severe in outline, aristocratic, but lacking strength and boldness in composition. With the advent of the Victorian Gothicists the worn-out and debased Free Classic passed into obscurity, there to remain until the

passage by Parliament of the Elementary Education Act in 1870 brought it once more into prominence.

But for all this cursory description of an eventful period Queen Anne has a history, architectural as well as political. Her short reign witnessed the erection of a class of manor-houses and city dwellings which, gradually improving under the two succeeding monarchs, proved the basis for a revival of a remarkable character. Let us then attempt to define the position of Queen Anne architecture historically, constructively and æsthetically, and see what may be its claim to our notice as a basis for the architecture of to-day, and wherein lies the germ that may be utilised as a stepping-stone to greater excellence.

History.—The reign of Queen Anne occupied almost exactly the first twelve years of the eighteenth century (1702-14). It was immediately preceded by what some architects call the Dutch William era, which as a reign may be called the last twelve years of the seventeenth century (1689-1702). Following these came the Georgian period, which was simply a development of the preceding, and lasted with some variations, although rapidly deteriorating under the last three monarchs, until the advent of the Victorian Gothicists. Perhaps the best way to illustrate the different phases of Free Classic will be to group the reigns of William and Anne in one period of a quarter of a century, half in the seventeenth and half in the eighteenth, following the Stuart or Jacobean and preceding the Georgian.

At first sight there appears to be little promise of finding any genuine art in English work of this period. The Mediæval ecclesiastical style had died out nearly two hundred years before; during the whole of this interval the revival of Classic architecture had steadily advanced from small beginnings to a respectable position, and an academic system, so to speak, which, although it never attained in England the appreciation which led to its luxuriant development on the Continent, found expression in many works of dignity and excellence. During the reigns of Elizabeth and James I. a domestic style for manor-houses had sprung up, based upon Gothic traditions of the Tudor type, with an admixture of the Renaissance of that day. This transitional manner struggled through the Commonwealth comparatively undisturbed, losing by degrees all traces of its Mediæval origin. It maintained, however, partly by the intention of its designers, but chiefly through accident, a character of picturesqueness and homeliness.

The Great Fire of 1666 desolated two-thirds of London, destroying 13,200 houses and 89 churches, including St. Paul's Cathedral. Down to this time the architecture of London had been mostly of the timber, brick and plaster type of the Tudors. The houses were crowded closely together, covering every available piece of ground and overhanging storey above storey, until in many cases the daylight was almost excluded from the narrow courts and crooked alleys. Many of the houses were of slight materials, covered on the exterior with painted planks and on the inside with plaster.

During the reign of James I. it was enacted that the fronts of City houses should be of brick or stone. In many cases, however, a compromise was made in favour of heavy timber fronts, often richly carved and moulded, the panels being filled with bricks and plastered, the sides away from the street being still built of wood. In these houses we find many examples of the picturesque oriels and windows adopted by the designers of the Queen Anne revival.

The Fire wrought a complete change in building construction and in the health of the City. The streets and courts were widened and improved and a new class of buildings arose above the ruins. It is with these buildings that we have to do.

Immediately after the Fire a proclamation was issued by the king giving instructions for reforms in building construction. This may be called the birth of the movement which developed into the Queen Anne style as we now know it. "In the first place," writes the king, "the woeful experience in this late heavy visitation hath sufficiently convinced all men of the pernicious consequences which have attended the building with timber, and even with stone itself, the notable benefit of brick, which in so many places hath resisted and even extinguished the fire, and we do hereby declare that no man whatsoever shall presume to erect any house or building, great or small, but of brick or stone, and if any man shall do the contrary the next magistrate shall forthwith cause it to be pulled down, and such further course taken for his punishment as he deserves, and we suppose that the notable benefit many men have received from those cellars, which have been well and strongly arched, will persuade most men who build good houses to practise that good husbandry by arching all convenient places."

By an Act of the Common Council, passed on April 29, 1667, in furtherance of the king's proclamation, it is ordered, among other details, that the surveyors "do encourage and give directions to all builders, for ornament sake, that the ornaments and projections of the front buildings be of rubbed bricks, and that all the naked parts of the walls be done of

* An address by Mr. George C. Mason, jun., delivered at the Architectural School of the University of Pennsylvania, and published in *Architecture and Building*.

rough bricks neatly wrought or all rubbed at the discretion of the owner." Permission was at the same time given to enrich buildings by variety in the forms of roofs, balconies, &c.

The urgent demand for new edifices to replace those destroyed by fire and the necessity for observing strict economy in their erection precluded picturesque grouping and well-studied designs. The quaint but dangerous architecture of 1666 was rapidly replaced by rows of plain monotonous brick buildings, utterly devoid of artistic merit. In Cheapside and some of the more important thoroughfares the houses erected during this period were of a somewhat better character, taller and more elegant in design.

While improvement in the character of domestic architecture was thus hampered by economic considerations and an intricate system of land tenures, public and ecclesiastical architecture was greatly improved. The rebuilding of St. Paul's Cathedral and fifty City churches by Sir Christopher Wren marks an epoch in the history of the English Church which should not be overlooked. For the first time since the Reformation the planning and general features of church edifices were made to conform to the exigencies of the Protestant faith and a simplified ritual. Rarely has such an opportunity for distinction been vouchsafed to any architect as that which fell to the lot of Wren, and he proved himself adequate to the task. It is stated that during the last forty years of the seventeenth century no building of importance was erected in England of which he was not the architect. Had his design for a complete rebuilding of the burnt district been carried out, London would have risen from its ashes one of the most convenient and beautiful cities of the world. The edifices erected by Wren are models of their kind. A thorough constructor, he was not less an artist in his feelings, and boldly adapted the system of the Renaissance to the requirements of the time, modifying his details to meet the exigencies which arose. The Free Classic of Wren was certainly very different in conception and execution from the stiff and formal expression which we note in the works of his immediate successors, several of whom were men of marked ability. It was, moreover, immeasurably superior to the Classic attempts of the architects of the middle Georgian period, who, carried away by the enthusiasm awakened by the perusal of the "Antiquities of Athens," published 1762 by Stuart and Revett, attempted to adapt Doric porticos, hexastyle, octastyle, &c., to modern domestic architecture.

With the accession of William and Mary England and the Continent became more closely united. French, Spanish and Florentine styles of dress became the fashion, and furniture designed in Flemish and Dutch workshops succeeded the heavier examples of the preceding reigns. The opening of the china trade and the importation of Delft porcelain exerted also an influence upon the tastes of society. An affected admiration for Dutch topiary also became the fashion. It flourished for a time and reached its limit of quaint absurdity in the reign of Queen Anne. She also set the fashion of collecting old china and bric-à-brac, and court etiquette demanding a reflex of the sovereign's tastes, china collecting became a craze, rivalling the tulip mania of Holland. Architecture also felt the influences of the Dutch school; brick was by law and custom the vernacular building material of London, as of the Netherlands, and high-stepped gables with wavy lines became frequent. Broken pediments with volute terminals were placed on doors and windows, while a slight admixture of wrought and moulded bricks was often added to give some degree of elegance and richness to the façades. This use of moulded bricks had played a prominent part in Tudor works, but the legislative wisdom of Parliament placed heavy and almost prohibitory taxes upon their manufacture and also upon glass, thus vitiating popular taste by the necessity of studying strict economy in construction.

The manor-houses erected during the reigns of William and Anne and the early Georges were of a different type. Those remaining to us are bold and massive, picturesque in outline, and semi-classic in detail. In these great palaces, for many of them rise to that dignified position, of the type of Blenheim and Castle Howard, the mass of the building is generally of stone, heavy and cumbrous, and displaying little of lively imagination in their groupings and general character. Their details are carefully modelled after the rules laid down by Palladio and Vignola, and their carvings and sculpture bear the stamp of Grinling Gibbons and his pupils.

Through the later Georgian reigns and that of William IV. the taste for Free Classic continued, gradually becoming more and more debased, with a few attempts at a revival of Mediæval work as attempted by Walpole at Strawberry Hill; while in London the school of Nash and Wyatt were stuccoing the honest brickwork of their façades with poor imitations of Roman palaces, which called forth such epigrams as—

Augustus of old was for building renowned,
For of marble he left what of brick he had found.
But is not our Nash a still greater master?
He found London brick and will leave it plaster.

The earlier years of Victoria's reign were marked by aspirations for a better state of things, and discussions between the rival schools of Classicists and Mediævalists. The latter carried the day, and, after an heroic struggle, England arose from her long lethargy to find herself the possessor of a noble architecture, a true exponent of ecclesiastical art and traditions, although confessedly far from perfect when applied to domestic buildings. For these latter edifices the old manor-houses with their many mullioned windows and Tudor arcuation formed the basis for design, and machioli, turrets and open timber roofs became the fashion for country houses. City dwellings were erected in a style that was a compromise between the Georgian and semi-Gothic, the most difficult problem being the reconciliation of the double-hung sash window with the pointed arches of Mediæval precedent.

English architecture was in this transition state when Parliament in 1870 passed the Elementary Education Act. This was the initiatory movement for the revival of Queen Anne or Free Classic architecture. By this Act the formation of local school boards was ordered, which called for the erection of many buildings, city and suburban, of a class hitherto but little known. Here was the opportunity long waited for, and architects seized upon it with avidity. The natural desire was to mark the period as an architectural era; to give to the Board School buildings a character distinctively their own, simple in plan and construction, with but little display and built of the vernacular material of English cities—red brick. Moulded bricks could then be obtained in abundance, the tax on their manufacture having been removed in 1850.

(To be continued.)

EVOLUTION IN DECORATIVE ART.*

(Concluded from last week.)

I NOW propose to give some instances of the development of certain ornamental designs with a view to illustrating some of the many causes which either dictate the primary form of the design, or which affect its after developmental history, and regulate the changes undergone by it. I will first take as my examples designs whose primary motive is a representation of human or animal forms, and I include for sake of brevity, both would-be realistic and grotesque treatments of these themes. I begin with a case from savage life, in which we may see successive changes apparently due to the individual tastes of the artists, though it is probable that there may have been the very usual utilitarian value for the variations as marks of ownership, as where the objects, spears in this case, were very similar, they could be individually recognised by their ornament. The patterns which I show are carved upon the shafts of spears from the Solomon Islands, always at about the same place.

In the first we can recognise a little grotesque human figure with very large angular mouth. In the second we see that while the body and limbs are vanishing away, this prominent mouth is reduplicated. The third shows three chevron-like mouths and but scanty remains of body and limbs. In the last example the "mouths" have completely gained the day, and form a series of chevrons, with a corresponding number turned the other way for symmetry. A few lines only at the base represent the last struggling remnants of the lower parts of the body. Although I do not pretend that these patterns are strictly consecutive, there can be little doubt that they are closely related and that the order of their appearance has been as described, the more realistic preceding the more conventional.

In the same group of islands one may see designs representing the frigate bird in all stages between very fair realism and complete conventionalism. The stages which are midway between the realistic and the fanciful are interesting, as, while the prototype of the design may still be recognised, one may at the same time see to some extent the direction whither it is tending in its passage towards a purely meaningless pattern whose resemblance to a natural object has entirely ceased.

I give an example from West Africa of two little carved wooden human fetish figures with long horns, the one showing body and limbs complete, the left hand holding the bowl of a pipe which is being smoked, and the other figure showing the same design in a more conventional form, the body and limbs fused into a mass below and the pipe hanging centrally between the mouth, or rather chin, and this body mass.

The human form in its treatment for decorative purposes undergoes marvellous vicissitudes, and affords, perhaps, the most striking instances of the effect of successive copying when the object is to create slight variations, often in order to produce a greater ornamental effect. When we look at the marvellously intricate scrolled patterns, carved with great skill by the Maories of New Zealand, we can see that there is a general relationship in their character, and if we take a

* A paper by Mr. Henry Balfour, M.A., read before the Applied Art Section of the Society of Arts.

sufficient number of examples, and classify them carefully so as to form more or less consecutive series, we can see that in nearly all cases the pattern of the scroll-work, however intricate and fanciful, is referable to one primary theme—a representation of the human form. Sometimes it is the face only, the beautifully tattooed lines of which readily lend themselves for transference as ornamental effects to materials such as wood-work; in other cases the body and limbs have also been brought into the design, and may still be recognised in the less fanciful examples. In the very conventionalised examples the nature of the primary conception can only be interpreted by an examination of other allied designs which have retained something of the original form.

Often enough, instead of an amplification of a design, or the retention of its more decorative elements, we see a process of degradation in the history of a design. The parts gradually drop out—it may be through careless representation or it may be through accident—and disappear one by one till there is no trace left. One notices the effects of degradation processes in the well-known “face vases” of Mykenar, in which the last remnants of what once represented a female head and bust are too little dabs representing the breasts, with no context to explain their origin, which can only be discovered by examining a number of examples of earlier date.

In the case of some ornamental designs there is a definite reason for creating variations. The case of the Japanese family crests, for example, supplies us with excellent instances of necessary variation from the original form of the crest, as new branches have arisen of the family, each demanding a fresh variation upon the emblem of the original family stem. The new design must be closely allied to the original, but must be sufficiently distinctive to denote a particular family branch. The crane, which, as emblem of longevity, appears in realistic form so frequently in Japanese art, is the original subject of one series of family crests, and becomes by successive modifications a kind of floral calyx upon a stem. The axe is another token, so to speak, and in some of the variations upon this theme we see a number of axes arranged around a centre and forming a kind of rosette; the handles in some cases nearly or quite disappear, and it is difficult to recognise an axe form at all in the later modifications. So, too, we may see floral designs derived from butterflies, and so on in endless variety.

The tendency for the more important portion of a symbolic design to persist, while the rest may disappear, has its curious illustrative instances, of which I give one. A common design in Maori art is one representing a face, with a tongue enormously protruded. This protruded tongue is symbolic, and is intended to convey the expression of defiance to an enemy. Hence the tongue is the most important feature represented, and it is essential that this should remain intact, though it matters less what becomes of the other features of the face. This minor importance of the rest of the face is exemplified in the three figures representing this design upon the tops of Maori ceremonial staves. In the first, a grotesque full face is seen, with the tongue of huge size and duly protruded. The second is seen to have the face in profile, though the tongue remains full face, this showing how little the eyes and nose and mouth are concerned in the symbolism of the design. The third example shows the complete suppression of face, while the tongue remains unchanged, and conveys its meaning just as well as ever to one who knows the origin of the design. So it is with other symbolic designs, which, although they have a definite and important meaning to convey, are liable to extensive variation; but while the parts of lesser importance may disappear early, the more strictly symbolic portions are usually the last to become modified, and these tend to persist, in spite of the disappearance of their context.

A constantly occurring cause of variation is the influence of one design over another. It is a matter of difficulty to discern the extent to which this takes place, but in some cases it is very obvious, especially so where two or more designs of different nature are subject to constant repetition in close proximity. Thus Haddon,* in describing the very elaborate dancing-masks of tortoiseshell made and used by the Torres Straits islanders, mentions that some of these are in the form of crocodiles, while others represent the shark. The influence of this latter design over the former seems to appear in the presence of lines representing gills upon the crocodile figures. Now, gills are in no way legitimate attributes of crocodiles, and one must suppose them to have been borrowed from the shark designs, in which they have a true morphological value. I must be content with giving this single instance of a very common factor in creating variation from the normal in designs.

The nature of the material is apt to dictate the form under which a design may appear, and the artist may be compelled to depart from anything like realistic representation by reason of the limitations imposed by the kind of material in which he is working. In textile art this is especially apparent; in the coarser form of textiles it is impossible to represent curves, and

it is in the finer forms alone that they can be represented with any degree of accuracy. This is very apparent in basket-work, and it is interesting, in the case of patterns or designs whose meaning we can recognise, to see how far their form is due to the essential structure of the fabric. The rectangularity which, perforce, must take the place of the curves which are often intended, is especially striking in designs whose motive is a representation either of animals or the human form. However desirous the artist may be to produce true resemblances, a grotesqueness of treatment is imposed by the nature and coarseness of the textile. In the decorative designs found on the basket-work of the natives of British Guiana, animal forms may often be seen—birds, frogs, monkeys, snakes, &c. The coils of a snake become a kind of a meander or Greek fret pattern, the curves being all squared. In some snake designs from British Guiana, the tails of the snakes being confluent, a nearly complete continuous meander is formed round the basket, broken only where the two heads of the snakes are represented. In other cases the heads are omitted and an unbroken fret pattern is formed, running continuously all round. That actual representation should readily give place to fanciful patterns is only natural where the best efforts at producing realistic figures can but result in the grotesque at the outset. Designs woven in cloth, carpets, tapestries, &c., show the same limitations in varying degree. Those of fine texture only admit of curved and scrolled designs of such exquisite beauty as some of those described and figured by Mr. Paul Schultze in a paper read last year before this Society.

I now wish to leave the consideration of designs whose primary motive is portraiture, and especially the representations of the human and animal form, in order that I may be able to give a few instances of ornamental designs whose actual origin as such is to be accounted for, which have, in fact, a definite *raison d'être* in the form in which they occur, as a reminiscence of their antecedents.

Where the circumstances have changed, we may frequently learn something of the earlier condition of objects by means of an examination of the form of decoration exhibited by them, and ornament thus becomes a useful clue in studying the developmental changes undergone by various objects. It is a common thing to see as a decoration upon vessels of clay a band of rope-like appearance running round the vessel towards the upper part. Now, in cases where clay of a poor quality has been used there has often been the custom of using plaited or twisted bindings in order to preserve the shape of the vessel before baking, and to prevent its collapsing. These bands would leave an impression upon the soft clay, which would be perpetuated in the baked vessel; and no doubt the rope-like bands of ornament, such as we see in the Zûni urn, were suggested as a form of decoration by the actual bands formerly used, or their imprints in other vessels. Such bands are frequently to be seen adorning, and seemingly giving support to, the coarse pottery urns of the ancient British times.

Where the material used in the manufacture of objects of use has been changed, the form imposed by the earlier material is frequently recalled in the decoration of the new material. To take an example: the natives of the Andaman Islands were, as they still are to some extent, in the habit of using the large shells of the bivalve pinna as plates for food; these are broad and rounded at one end, and pointed at the other. They have now largely substituted dishes made of wood for these shells, and these wooden dishes are pointed at both ends, but in some the shape of the shell is suggested by the presence of a curved line in wax at one end, which seems, as it were, to cut off the pointed end beyond it, and to give the shape of the shell prototype. There can be no other reason for this curved line at one end. Another example may be seen in the little “apple-gougues” still to be seen in use in the country, made from the shank-bone of a sheep, partly cut away to form a long narrow gouge-like blade, and with a handle formed by the natural articular condyles of the bone. Some of these instruments are made of wood, instead of the natural bones, but, though these may be more elaborate in make and decoration, they nevertheless, in their general shape, simulate the bone shape, and the two articular condyles appear as an ornamental shaping of the handle end.

In cases where an object of use has for various reasons changed its structure somewhat, while retaining its general shape or appearance, we may sometimes see instances of decoration which have been suggested by former details of structure which have been suppressed on the new forms. Thus, there is the case of some air-guns, with which some time ago an Austrian regiment was armed, in the place of the more usual firearm of the period. These being air-guns no longer required to be fitted with an external lock and lock-plate, but the absence of the latter seems to have been regarded as detrimental to the appearance of the weapon, and we find the outline of a lock-plate engraved upon the breech end of the gun at the point where the actual plate would have been had the propulsive agent been gunpowder. I am not sure that some of our modern “hammerless” guns do not show some-

* *Internat. Arch. f. Ethnographie*, vi. p. 146.

what kindred external ornamentation. A very similar case of "survival" in ornament is seen in some well-known Greek and Etruscan helmets, in the early forms of which we see a space between the cheek-pieces communicating above with the two eye-holes, which are separated by the bar protecting the nose. Modern tailors perpetuate the memory of what was once a useful appendage to a coat, when they add as finishing touches the two buttons which we see upon men's coats in the region of the small of the back, and the shape of the coat collar and flaps is often only suggestive of a possibility of buttoning the latter across the chest when desired, as the shape is just sufficiently modified to prevent this being actually done, the button-hole being solaced for the loss of the button with which in former times it would have been mated by being made the recipient of the small bunch of flowers which adopts the name of its holder.

I will now conclude with an example of a form of decoration which owes its origin accidentally to a process in the manufacture of the objects which it adorns. The natives of the Solomon Islands, from whose art I have already drawn more than one example, make their long arrows with shafts of bamboo. The roughness of the nodes upon the bamboo proving inconvenient in shooting, these are usually pared down so as to render the whole shaft smooth. The fibrous structure of the bamboo causes a liability for narrow strips to peel away when started by a cut, and we see arrows in which numerous narrow lines of varying length are grouped round the node caused by this accidental stripping. In the course of the use of such an arrow the stripped portions become darkened, as they readily take up any dirt or other colouring matter, whereas the smooth siliceous exterior remains clean. These darkened groups of long and short lines were evidently accepted as a suggestion for decoration, as we see that they have been copied with a more careful regulation of length of the lines, which are grouped in graduated series and purposely darkened with black pigment. The paring of the node is performed by a separate process, with greater care to prevent peeling as before, in order not to encroach upon the derived ornament. Next came an increase in the number of the groups of lines, which are now often produced by scraping and not peeling. At a later stage the lines are finely incised, the number of groups increased, so that their bases become fused. Later still, the groups are more completely fused, their apices alone being separate; and lastly we get complete fusion, the lines, all now of equal length, forming a complete band round the shaft, just above the node. This band appears under a great many varieties, in accordance with the varying tastes of the artists.*

In bringing to a close this very brief and imperfect survey of a wide subject, I will only add that although I have, in order to avoid possible complexity, selected for my illustrations of the various developmental processes examples taken for the most part from the art of the lower races of mankind, the same processes may be seen at work in the art of the most highly civilised people with much the same results, and we have only to study with a little care the examples of decorative art which everywhere surround us, and are always at hand, to discern traces of a developmental history which is often as startling and curious as it is interesting and instructive.

HOSPITAL CONSTRUCTION.

A MEETING of the Leeds and Yorkshire Architectural Society was held on Monday evening in the Law Institute, Albion Place, when Mr. W. Henman read a paper on "Hospitals." He said that much information was available on the subject, but future scientific investigation would no doubt demand the relinquishing of opinions now held and the substitution of others. To gain a proper knowledge of the subject they must ascertain what failures there had been, and seek out the defects of the existing buildings. He strongly advised such personal examination, as well as inquiry of doctors and nurses, as to good and bad points. The public demanded that the external aspect, as well as the inside, should receive attention. They had to secure the health and happiness of the patients and staff, and also an artistic exterior. Mr. Henman referred to the two systems of artificial ventilation in use—air taken out by suction, and air forced into a room. He explained the ventilation of the hospital at Birmingham now being constructed from his plans. There the air, warmed, freed from dust and insect life, will be sent into the ward and extracted by means of a fan. Ventilation of a similar character is in use, he said, at the Victoria Infirmary at Glasgow, and it works exceedingly well. In hospitals it was desirable that the air should not circulate from ward to ward, and for this the system provided. A vote of thanks was accorded to Mr. Henman.

* This series was originally published, with a plate, in the *Journal of the Anthropological Society*, xvii. p. 328.

Tendering in Aberdeen.

SIR,—In your issue (early in January of this year) you published a list of the tenders which had been received for the Broomhill School (under the Aberdeen School Board) and the names of the successful offerers.

If you will kindly refer to the list of offerers for iron-work, you will note that the offer of our firm, although the lowest, was not accepted. Being quite unaware of any reason why we should thus be passed by, our law agents wrote to the Clerk of the School Board asking the reason, but failed to get any explanation.

The School Board election here is now coming on, and we send you by this post a copy of the *Aberdeen Free Press* giving a report of an election meeting at which Mr. James Smith, one of the members of the present Board, gives an explanation of the reason why our offer was not accepted, and at same time states that after investigation he found there was no ground for the defamatory statement which had been given to him as the reason for not accepting our offer.

As the publication of this action of the School Board in your paper caused us considerable loss and damage in reputation, we shall esteem it a favour if you will be good enough to insert some explanatory statement from the paper we send you. Thanking you in anticipation, we are, yours faithfully,

BLAIKIE BROS., Ltd.
(C. Wilson, Sec.).

Aberdeen: April 14.

[We are not responsible for the decisions of Local Boards, School Boards, County Councils, &c., though we have to record them. It should be well known by this time that frequently advertisements are sent to the press as a mere matter of form, and therefore it is not known that those advertising have already selected their man to whom they have decided to give the job or the appointment. As to the merits of the above, we express no opinion till we have further looked over the evidence.—ED.]

GENERAL.

Mr. George Simpson has been recommended as the new burgh assessor, architect and practical adviser to the Leith Town Council, but he is not to conduct a private business, unless as a valuator of private property. The salary will be 350*l*.

The Architects who have been elected to serve as jurors for the forthcoming Salon exhibition are MM. Daumet, Coquart, Ginain, Vaudremer, Pascal, Guadet, Mayeux, Laloux, Loviot, Garnier, Raulin and Corroyer, with MM. Esquié and Deslignières as supplementary jurors.

The Bella Houston Trustees have offered to the Court of the University of Glasgow a grant of 5,000*l*. towards the erection and equipment of buildings at Queen Margaret College for the medical and scientific instruction of the students, provided the Court is willing to undertake the pecuniary responsibility of erecting the buildings in question.

Mr. C. C. Doig, architect, Elgin, has patented an invention for the prevention of fire from explosions in malt mills. It consists of a specially made conveyor set in a suitable position underneath the cylinders of the mill, and having the blade of the spiral cut at such a point that, whether the mill is running full or empty, there will always be a seat between it and the elevator or hopper, thus localising and extinguishing any slight explosion that could possibly occur to its seat.

The Great Bell offered by the citizens of Moscow to the Parisians, which will weigh 80,000 kilos, or nearly eighty tons, is to be placed in the new church of the Sacré Cœur, Montmartre. It was too heavy to be used at Notre Dame.

The Burns Statue in Ayr will soon be complete, two of the four panels having been placed in position. One is the gift of the sculptor, Mr. Lawson, and represents the ride of Tam o' Shanter; the other is the gift of Mr. Birkmyre, M.P., and represents a scene in the "Cottar's Saturday Night." The third panel has been subscribed for by the Freemasons of Scotland, and it is probable that the fourth will be the gift of the Ayr Burns Club.

A Series of Illustrations by Mr. H. P. Burke-Downing, of the principal abbeys and minsters of England, has been commenced in the new magazine *St. Paul's*.

Professor A. W. B. Kennedy, President of the Institution of Mechanical Engineers, presided at the annual dinner of that body, held at the Freemasons' Tavern.

The Liverpool City Council have decided to invite the British Association to hold their annual congress for 1896 in Liverpool.

The Architect.

THE WEEK.

THE competition among sixty-one architects for a school in Fulham Palace Road to accommodate 1,200 children, and that could be enlarged to accommodate 1,600 children, which was decided at the end of last year, was not quite so satisfactory as was expected. General MOBERLY, the chairman of the works committee of the London School Board, and Mr. HUGGETT, have declared that, "after a careful examination of the premiated designs, there is not, so far as we are able to see, any new feature, educational or otherwise, in any one of these designs;" "that the adoption of the designs would not effect any reduction in the cost of such schools and buildings;" and that "there are certain features in the elevation of this school, such as the multiplication of gables, which would tend to increase the initial cost of building, and would materially increase the cost of subsequent repairs, besides having the effect, in the case of the windows, of somewhat interfering with the efficient lighting of the school, inasmuch as the corners of some of the rooms would be indifferently lighted, and the windows themselves contain very small panes in accordance with the style of architecture adopted." If one of the plans were carried out the commission to the architect would be 5 per cent., while the architect's department can carry out building at a cost of about 3 per cent. on the outlay. That saving is, however, so insignificant if compared with the outlay on other experiments, we are surprised it was mentioned. The competition cost the Board 552*l.* 14*s.* 10*d.*, the principal items being the three premiums amounting to 300*l.*, and the assessor's fee of 200*l.*, and as in the opinion of the committee the only gain from the outlay was the gratification of discovering that the Board's plans are not to be surpassed, the chairman of the works committee proposes that the authors of the three premiated designs be informed that the Board do not propose to take any further action in the matter. One of the members of the Board will propose as an amendment that Messrs. MITCHELL & BUTLER, Messrs. CRICKMAY & SONS, and Messrs. LEEMING & LEEMING should each be instructed to prepare plans and specifications for a school on the lines of their design, but that in the event of the tenders exceeding their estimates, the engagement shall be cancelled without the Board incurring any liability. The conditions of the amendment cannot be considered as too generous, but if the three firms will accept them they ought to have a chance. The criticism on the designs would enable the architects to remove defects, and it is possible that three efficient schools would be erected. For the sake of saving 2 per cent. on the outlay the London School Board should not leave an experiment incomplete.

THE cases which turn on questions of efficient drainage in houses have become so numerous, we may soon expect that the least suspicious lady will realise the necessity of obtaining a guarantee of the sanitary arrangements before taking a house. On Monday Mr. Justice ROMER tried an action, TOFIELD *v.* ROBERTS, plaintiff and defendant being ladies, which was a revelation of the diffusion of knowledge concerning law. The defendant was eager to obtain a house in the West-end for her daughter, who was about to be married to a Captain SOMERSET. The plaintiff was willing to dispose of the lease of a house which suited. In a letter to the house agent, Mrs. TOFIELD said, "I can give assurance that the drains are satisfactory, as I had them looked at a year ago, when certain alterations were made, and all that was necessary was done." The defendant did not appear to have accepted the assurance as sufficient, for she had the drains examined. Then a promise was given to buy the interest in the lease, and a deposit was paid. Captain SOMERSET wished to have electric light in the house, and although no contract was entered into by him, the electricians commenced operations. Occasional visits to the empty house did not convince the defendant that the drains were innocuous. There was a new examination ordered, and their defects were manifested. The

defendant accordingly declined to carry out the agreement, on the ground that there was misrepresentation, and the action was taken to compel her to purchase the lease. There were two points in the plaintiff's favour—first, the want of confidence shown by the defendant, who, after receiving an assurance about the drains, ordered an examination of them, thus suggesting that it was understood there was no absolute guarantee. The second was the starting of operations for the electric lighting, which might be taken as part performance of the agreement between the parties. Mr. Justice ROMER would probably have given judgment for the plaintiff on the latter point if a contract had been entered into for the work. But in the absence of such a document, there was nothing to connect the plaintiff with the operations. The suspicion about the drains was not interpreted by the judge as the entire absence of reliance on the assurance; besides, it was confirmed by a statement of the agent's about the condition of the drains. The plaintiff therefore lost her action. It must be said, however, that very little would have sufficed to have brought about an opposite result.

THE recent depression in business was not without effect on the finances of the Art Union of London. The report which was read at the meeting on Wednesday states:—"The serious financial crisis in the Australian colonies produced a marked effect upon the returns of members furnished to the Society last year. The great coal strike has had a similar effect in many of the northern and midland districts of England upon the amount of support extended to the Society, and therefore it is gratifying to the Council to be able to announce an increase in the subscriptions for the year now closing, and a considerable accession of new members to its ranks." The Marquis of LOTHIAN has been elected successor to the late Earl of DERBY, and under the new presidency the Art Union may be able to advance at a better rate than was witnessed recently.

THE exhibition in the Champ de Mars contains this year eleven works by the president, M. PUVIS DE CHAVANNES. They form part of the decoration of the Hôtel de Ville, Paris. The largest will be *Victor Hugo Offering his Homage to the City of Paris*, which it must be admitted has disappointed the admirers of the artist, although it may appear less odd when attached to the ceiling of a staircase. For the six tympanums the artist has selected the following subjects, viz. *Beauty, Fancy, L'Esprit, Remembrance, Urbanity and Intrepidity*. The subjects for the voussours are *Patriotism, Charity, Enthusiasm for Art and Intellect*.

THE inquiry before Mr. P. E. PILDITCH into the claim made by Mr. NIGHTINGALE against the London, Liverpool and Globe Insurance Company has been concluded, after occupying eight days. The case related to the reinstatement after a fire of a large grain warehouse at Rotherhithe, and occupied by Mr. GORDON COMBE. The builder's claim amounted in the aggregate to about 8,000*l.* Among the witnesses were Mr. A. R. STENNING, Mr. TAVENOR PERRY, Mr. NIGHTINGALE, Mr. FRASER, Mr. RICHARD MORLAND, C.E., Mr. G. WAILES, Mr. SIDNEY YOUNG, Mr. JOSEPH OAKE, Mr. W. A. REES and Mr. F. W. PORTER. The amount awarded was about 1,200*l.* in addition to a sum of over 3,000*l.* received on account.

MESSRS. HOMAN & RODGERS have had an ivory set-square prepared for the use of their customers. The material is well adapted for the purpose, for it is smooth and cleanly. The square has the additional advantage of furnishing the safe loads for steel joists, varying from 5½ to 19¾ inches in depth. The information is constantly required in architects' offices, but too often it is not easy to discover where it is to be found. Messrs. HOMAN & RODGERS supply it in a form that will always be at hand. The square is therefore useful, as well as a luxurious addition to drawing instruments.

DEFYING AUGURY.

THE laws against fortune-telling and the general aversion to gipsies who are associated with palmistry have not eradicated the belief in divination. Although the age is supposed to be scientific, and in consequence takes nothing on trust, yet there is evidence enough that hard-headed people, in spite of all their respect for logic, have a lurking faith that the mysterious laws prescribed by fate respecting individuals are to be discovered. Professors of phrenology, sages who can read the lines inscribed on the hands or the feet, interpreters of handwriting and others of the same class, manage to inspire as much confidence as if in conducting their researches they observed the Methods of Agreement and Difference, of Residues and Concomitant Variations. There must be something inherent in human nature which finds gratification in every sort of revelation about so mysterious a being as man himself, and in anything which is supposed to afford a clue to his nature and its capabilities for good or evil.

All professors of the kind are, however, liable to be treated as charlatans so long as they confine their attention to individuals. But if while acting in precisely the same spirit they attempt to tell the fortunes of nations under the guise of the philosophy of history or some sounding designation of the sort, they may with some confidence lay claim to the respect of their contemporaries and the reverence of posterity. Their predictions may not be more certain than those which gipsy women unfold on a race-course, but so long as people are flattered by them the end of the seers is attained.

At the present season the recollection of some of those predictions must arise, for it is a remarkable fact that every exhibition of the Royal Academy, as well as of other societies, or even one of rejected pictures, is evidence of the baselessness of the laws which philosophers have affirmed to be preordained for the government of the world. If those keen-eyed men were right, a Briton is incompetent to paint a picture or to produce a work of art of any class, and his efforts are a sort of rebellion against the system of the world.

According to Mr. FERGUSSON, "wherever the Aryans appear, art flies before them," and he gets over the instances in which art was less fearful, or was not furnished with wings, by ascribing them to accidents, as when he says, "Had there been no Pelasgi in Greece, there probably would have been no architecture of the Grecian period." As he arranges the inhabitants of the world, past, present and to come, in only three or four groups, they resemble generalities, and the people of one country cannot be elevated at the expense of others. His conclusions are like the fortune-teller's declarations about the enemy or rival that is to appear at some indefinite time, but is not necessarily the BROWN, JONES or ROBINSON who is detected at the moment by the seeker after knowledge. The Aryans are a tolerably numerous family, and Britons have no right to assume that Mr. FERGUSSON was jibing them alone when they occasionally assumed they were creating works of art while engaged in a slovenly process of copying.

The philosophers of the last century, on the contrary, were precise, and pointed to the inhabitants of the British Isles as affording an unquestionable proof of the wisdom of Providence or nature in depriving people of capacities that would be useless to them. MONTESQUIEU was one of those wise men. He came over to England in Lord CHESTERFIELD's yacht in order to study the people and test the accuracy of his conclusions about their peculiarities. He was presented to GEORGE II., the Queen and Prince, at Kensington. For his sake the conversation took a literary turn. He heard Queen WILHELMINA CAROLINA ask Lord CHESTERFIELD why all SHAKESPEARE's women were stupid, and, as a further display of her ability, Her Majesty condescended to ask MONTESQUIEU whether in France CORNEILLE was not preferred to RACINE. In his pursuit of knowledge MONTESQUIEU did not hesitate to drive through the streets of London, although he knew it was necessary for a man to make his will before he entered a hackney coach. He endured much, but at least he witnessed remarkable scenes, which he turned to account, such as the slaters reading their newspapers on the roofs of houses, and the stout member in the House of Commons declaring again and again that in England there was no

need of troops, and that he did not care to be governed by Hanoverian maxims. But all the eccentricities, as well as the peculiar virtues, he charged against the climate. In England it gave rise to a malady which was persistent, and made the inhabitants disgusted with life. Every one was afflicted, and as they found some little relief in abusing the climate, as well as all things created, it was necessary that there should be freedom to speak as one pleased and do as one liked, even to the extent of committing suicide. There was no sacrifice which the Briton was not ready to make to secure that relief. Sometimes his patience was exhausted, and to escape from the climate he went to some distant part of the world and founded a colony. There might be less oppressive air in the new region, but habit asserted its strength, and the emigrant was unaltered. England was, however, to be watched by all its neighbours, for men who lived always in so unenviable a state would be glad of opportunities to gain excitement. Hence the people were feared by others. The heaviness of the climate was not without effect on luxury. Everything ministered to pride; there was no demand for anything that was light or frivolous. There was bitterness in the works of literature, and owing to the extent of corruption many English JUVENALS were to be found for one HORACE. The poets, being deprived of taste, were rude rather than delicate. The works of art displayed something which approached the force of MICHEL ANGELO rather than the grace of RAPHAEL. The people were so dense no wit could penetrate to their sensibility, for MONTESQUIEU records as if he were not satisfied that the only effect of his book was to make the English give orders for the wine he produced in his vineyards at La Brède, in the Bordeaux district.

In truth it was easier to treat the author as a shrewd man who wished to advertise himself and his claret than to reply to his arguments. Once admit that the climate of England is so depressing that the finer qualities of the mind have no chance of exercise, and it must follow that art and literature cannot thrive in England. MONTESQUIEU was a lawyer, a judge, a president of a French Parliament, and in his book he displays his practised skill as a dialectician. To give more effect to his reasoning he adopts a method that is almost as impersonal as EUCLID's. He does not always refer to a country by name; he prefers to say, in the case of England, Let us suppose an island exists in the northern seas with certain defects, inhabited by people with certain qualities, and so on, what kind of character and what events will follow? One conclusion comes after another until it appears to be unquestionable that the English must be a stupid race, who succeeded after an immense expenditure of blood in being governed by a stupid king who had a stupid son ready to succeed him. He relates how at a masquerade Lady DENHAM asked GEORGE II. what had become of the Prince of WALES, and if they were afraid to let him be seen, and was he to become "aussi sot que son père et son grand-père?" Princes, courtiers and people were alike afflicted. It was this rigorous reasoning of MONTESQUIEU which seemed to oppress JAMES BARRY, the Royal Academician, when he endeavoured to explain that there was no necessity to be desponding about the future of art in England, because of the degree of latitude which marked the position of the island. He acknowledges that MONTESQUIEU was unlike the other critics who saw no hope for England, and it was his power which deceived him. This is evident when we find BARRY saying, "Sometimes these eagles of philosophy will soar so high that they see nothing but clouds. A mere ordinary man would have found out, nay, had it been in the islands of Borneo or Madagascar, MONTESQUIEU would have found that this hateful practice of suicide was brought about by a combination of moral causes; that it was of very recent introduction, and that the natives formerly were not particularly remarkable for this moroseness of disposition and this *tædium vite*." BARRY's fastening on what was said by the Frenchman about suicide, which is only referred to as an occasional consequence of the miserable weather, suggests the difficulty of dealing with MONTESQUIEU's conclusions. Whether it is a philosopher, a fortune-teller, or Mr. FERGUSSON who attempts to predicate about Fate, a plain man is sure to be puzzled in replying.

WINCKELMANN was more impartial than MONTESQUIEU, for he believed that the entire north of Europe, including

Germany, was subjected by nature to restrictions which only an occasional genius could surmount. According to him, the influence of climate on the mode of thought of a people is just as perceptible as the influence of the same cause on their conformation. The Britons were, in consequence, sober-minded, and their reason predominated over their imagination. Even their poets could not suggest pictures. MILTON'S scenes, which are astonishing but fearful, are not fitted to be painted. With the exception of one scene in Eden they are all like Gorgons and all alike terrible. Whether the scarcity of painters among the English—for they could not refer to a single one who attained celebrity—did not also proceed from the climate, WINCKELMANN said he left to others to determine. Apparently he considered the subject was too trivial to occupy his attention.

The versatile Abbé Du Bos in the early part of the eighteenth century was the lawgiver on art in Paris. He was willing to admit that England produced excellent poets and musicians, as well as followers of science. But his list of the painters contained only three names, viz. COOPER, HUDSON and RILEY. The cause was the unlucky climate. The peoples among whom the arts have not flourished, he said, are those who inhabit climates which are unsuited to the arts; everywhere else they appear of their own accord, or can be introduced by the aid of commerce. Du Bos demonstrated that for two centuries at least before his time the English were lovers of pictures. A foreign artist could gain among them three times as much as with patrons elsewhere. HENRY VIII. treated HOLBEIN royally. Queen ELIZABETH for nearly fifty years was munificent in her dealings for *vertus* of all sorts. The enthusiasm of CHARLES I., and his ambition to outbid PHILIP IV. of Spain, raised the market prices of Old Masters throughout Europe. But in spite of the prodigality in spending money, not one Englishman arose who was qualified to be ranked among second-class artists; the three portraitists above-named represented native ability. Du Bos explains how the HOLBEINS, LELY and KNELLER came from Germany, VANDYKE from Flanders, VERRIO from Naples. The money and medals, as well as sculpture, were also the works of strangers. There were no better workmen than the English, but they were forced to depend on foreign workmen to supply designs. Du Bos considered there was one law for vegetation and painters. There were plants which could not grow outside the prescribed habitat, and however enormous the sums might be which were available to be expended on works of art, they were insufficient to create artists in lands which were humid or torrid. The characters of men corresponded with the climates in which they were nurtured, and as long as England was cold and damp there was no chance of possessing native painters: the patrons of art would have to rely on foreigners for gratification.

A theory which was so plausible could not fail to be accepted in France and it is not altogether exploded. The amazement expressed by the French artists and critics when they saw English pictures in international exhibitions in Paris was a proof of the conviction that England was not destined to be a mother of the arts. EDMOND ABOUT, for instance, could not help admitting that in 1855 there were capital paintings in the English section, but he consoled himself by denying there was any sign of genius in the collection. Unlike MONTESQUIEU, he was able to see evidence of *d'esprit* on all sides, and he prophesied that it would become from its profusion the ruin of the art. To the Frenchman the English school is a sort of baseless fabric, an exhalation which at one time does not appear to exist, and at another time and afterwards assumes the appearance of the most enduring stability. They are not to be deceived, however, and in the Louvre the English paintings are therefore remarkably few.

As we have said, it is not easy to argue with those who profess to have exceptional vision, which can pierce obstacles and read the future with as much ease as a novel. There is, however, one way of dealing with them. It is a puzzling process to prove the possibility of motion, for a thing cannot be in two places at once, but practically it can be demonstrated, *solvitur ambulando*. In the same way we can admit that in theory neither Englishmen nor Aryans have any authority from nature to meddle with art, and their efforts are like the planting of barren slips doomed to

failure. As Mr. FERGUSON asserts, want of faith will prevent the Aryans from attaining more excellence in architectural art hereafter than they have done in the past; they are singularly deficient in their appreciation of colours and the harmony of tints is unknown to them, while "an ideal statue or ideal painting may be a pretty Celtic plaything, but it is not what Aryans hanker after." The deductions from the laws of race as well as of climate therefore appear to be against the endeavours of the Aryans to become artists. But as HAMLET said, "We defy augury." If art fled before the Aryans it was easily captured and made subservient like other forces, and we may expect that in the future it will also minister to their needs. The productions may not be comparable to such Turanian examples as the tombs of ancestors in China or the cave temples of India. But in spite of their shortcomings beside those works which have the sanction of nature, they have character enough to inspire the hope that in spite of Mr. FERGUSON and the French philosophers, art in Britain, as in Germany and America may yet attain a level which will not be much below that of ancient Greece. Meanwhile, let us enjoy with more zest what we can see at the Academy and elsewhere. A new interest is imparted to the attempts in architecture, painting and sculpture by the doleful prognostics of the seers. If it be granted that in England we have not an aptitude for art, we can at least have the satisfaction of rising against the decrees of a pitiless destiny. The examples may not be equal to what are to be seen in the East, but as a manifestation of the strength of the Aryan will they are unmatched elsewhere.

GLASGOW ARCHÆOLOGICAL SOCIETY.

A MEETING of the Glasgow Archæological Society was held on the 19th inst. Mr. J. Dalrymple Duncan, hon. secretary, reported that a representation had been made by council of the Society on the subject of the proposed destruction of the island of Philæ by the raising of the level of the Nile for irrigation purposes.

It was also reported that a communication had been received from the Secretary for Scotland on the subject of the Antonine Wall, asking for a statement of those parts of the wall which are of special interest and best suited for protection, in order that it might be considered whether the owners of such portions of the rampart should be approached with the view of ascertaining how far they might be willing to agree to the application of the Ancient Monuments Act. The information asked for had been furnished, and it was hoped that the steps proposed to be taken might result in the preservation of some of the more interesting sections of the line of the rampart.

Rev. W. Lee Ker read a paper on "The Papingo." In introducing the subject, Mr. Lee Ker referred to a practice not unlike this pastime alluded to by Homer in his description of the games which accompanied the funeral of Patroclus. He also quoted from "Strutt's Sports and Pastimes" to show that the sport of the popinjay was well known to the Londoners in very early times, and mentioned a curious proviso which showed that the marksmen were protected against any harm done by their arrows, provided only they called out "fast" before shooting, just as a modern golfer fancies he can swing his driver as he pleases provided only he calls out "fore." Referring to the papingo, which is simply the Scottish way of spelling popinjay, it was noted as a strange fact that while this sport was doubtless very generally practised for centuries in Scotland, nevertheless nothing definite can now be learned respecting it except from records found in two neighbouring towns of Ayrshire, viz. Irvine and Kilwinning. Sir Walter Scott, indeed, in "Old Mortality," refers to it as played at Dalserf, in Lanarkshire, in the seventeenth century, and in Maybole at the beginning of this century, but even the traditions of these places afford no information upon the subject. An interesting paper was read showing that the paipingoe or papingo, for it is written both ways, was in full swing in Irvine in 1665, while the earliest record of the Kilwinning Archers states that on September 4, 1688, certain gentlemen "mett and conversed in order to the restoring of the ancient game of the papingo, formerly used to be practised in this place." Mr. Ker carefully considered a claim usually made by those who have written upon the subject, namely, that the sport was practised in Kilwinning as early as 1482. While admitting the possibility of this, he denied having proof for it, and so argued that Irvine and Kilwinning should be content to divide the honour of antiquity in connection with this matter between them, at the same time pointing out that the pastime was discontinued in Irvine probably about the year 1721, while it continued to be practised in Kilwinning till 1870. The

papingo, which was probably regarded as a mere pastime in connection with archery, was practised thus:—A piece of wood was formed so as to resemble an ordinary-sized parrot, and was attached to a pole, which in its turn was placed horizontally on an elevated place—in Kilwinning it was fixed on the tower of the old abbey, and was therefore 100 feet from the ground—the wings being at the beginning of the sport spread out and stuck loosely into the sides of the bird. The marksman stood at the foot of the tower, and therefore shot perpendicularly at the papingo. If he touched the bird with his arrow he got a prize, and if he winged it he got a larger one, viz. a piece of ribbon, which he proudly stuck into a button-hole of his coat. At the last stage of the competition the wings were taken out, and the bird itself “was made lower for shooting him af,” so that a slight touch of an arrow could “ding him doon.” In the olden times the prize given to the successful marksman was first and above all the honour of being captain of the papingo, and then, to distinguish him from all others, a piece of Persian taffetie, which he wore round his waist, and which was called a benn. In later times, however, the Persian taffetie was disused and a piece of silver was given instead, the cost of which was to be twenty shillings sterling. In 1724, however, a valuable silver arrow was presented by “David Muir, merchant in Kilwinning,” and this was so much thought of that the winner of it was not allowed to have it in actual possession, but only to retain it during the year of which he was the captain. Moreover, it was agreed that each successive winner of the arrow was to affix to it a badge of silver or gold “not under a crown value,” the result being that as time rolled on the old arrow could not hold all the badges and a new one had to be procured. When the pastime ceased 116 medals had been presented, many of which are very beautiful. The sport of the papingo was evidently regarded as a big business in early times, four days in Irvine and three days in Kilwinning being devoted to the sport, but from the beginning of the present century one day sufficed. At the gentlemen's papingo—for there was a men's papingo as well—all the county magnates presented themselves, though during the last years of the sport Glasgow gentlemen were the most numerous and influential. Jollity and mirth, dining and dancing, were the constant accompaniments of the festival. And yet it was all apparently very frugally done. It had to be frugally done. So far back as 1732 complaints were made of the smallness of attendance of members at the dinner on account of the expense, and the difficulty was got over by an arrangement that a dinner would be provided at the very moderate charge of 1s. each, “exclusive of wine.” But the captain had to pay up. His dinner must have cost him something, for he had to present a complimentary ticket to the parish minister, that grace might be properly said, and some other complimentary tickets besides. And he had to provide a bowl of punch to be drunk at the Crossbrae, and for this he had to pay one pound. True, there were privileges granted to him while the punch was being handed round. He had the honour of proposing prosperity to the trade and town of Kilwinning, and, at least in later days, he had the felicity of saluting the pouting lips of an aged lady of four-score years and tripping with her the light fantastic toe to the delight surely of himself, certainly of all present. And then there was the ball, without which no papingo day could be properly brought to a close. Evidently it was not everybody who could afford to be captain of the papingo. This sport of centuries terminates on July 28, 1870, though the men's papingo continued till 1877. The last medal was presented to the Society by Mr. James Hutton Watkins in 1866. The last captain was Mr. Neil, of Swinridgmuir, but as he was not present at the festivities of 1870, Mr. William Brown, of Parkend, presided. The records of the Society, the silver bow, arrows and medals are carefully preserved by Messrs. Hugh & Rob. C. King, bankers, Kilwinning, who are the heirs of the last secretary of the Society, the late Mr. Hugh King.

Dr. Murray, in proposing a vote of thanks to Mr. Lee Ker, said many must remember the archery meetings which took place in the Botanic Gardens at the end of Sauchiehall Street, and in Edinburgh the Royal Company of Archers was still a popular institution. He did not know that they shot at the papingo. There was a great deal of butt shooting in Glasgow. One butt stood behind the cathedral, another in the old barracks, and a third down at Stockwell; and one of the most serious riots which ever took place in Glasgow was in reference to archery shooting at the butts behind the cathedral. He did not know that they ever had the papingo.

Mr. Lee Ker, in acknowledging the compliment, said that archery shooting was practised in many towns in Scotland, but he had been unable to discover any trace of the papingo save at the places named in his paper.

Professor Young exhibited a collection of Roman coins found near Kirkintilloch. The collection was sent to the British Museum. One was retained. The ten shown were returned. Their interest lay in the fact that they present a consecutive series which ranged over about eighty years, the first dating

possibly 81, the last 161. They began with Domitian and ended with Antoninus Pius. The series was fairly complete of the currency of the empire during an important period of the occupation of Scotland. There was a coin of Adrian which was exceedingly interesting. The two coins of Antoninus were familiar enough types in the Roman series proper, but they presented a peculiarity which was frequent in provincial coins as being crenellated at the margins. The collection did not belong to him, but he hoped to acquire it with the permission of the authorities. The coins found in the neighbourhood of the Roman wall were not so numerous as one could wish them to be. There were several mentioned in Stewart's “Caledonia,” and he had discovered the *locale* of one of these coins and also of a ring. Professor Young also exhibited a series of casts of the numismatic history of Esculapius.

Votes of thanks were passed to Professor Young and to the Chairman, and the proceedings terminated.

CARPET DESIGNING.

A PAPER on “Design in Modern Carpets” was read by Mr. Alexander Millar at the meeting of the Society of Arts on the 18th inst. In the course of it he said:—

One of the charges most commonly brought against us is that we originate nothing good, that our best efforts are only feeble copies of Oriental or other ancient fabrics. Now, while this is partially—and it is only partially—true, I contend that even so far as it is true it is unfair. A test is applied to us to which other designers are not expected to conform. Take the art which is said to be the basis of all others. Are architects expected to design their buildings absolutely without reference to anything that has gone before? How do they train themselves for their work? Do they not study the great examples which have survived from the past, saturate themselves with their spirit, and fill their sketch-books with their details; and when they are called upon to design a modern building, do they not simply draw upon the store of material thus laid up, and evolve something suited to the special requirements of the case, but which in all its main decorative features is simply a reproduction of what they have assimilated, with something of their own superadded, the amount and quality of which is the measure of their originality? And in all this is not the architect of the present day simply following in the footsteps of his great predecessors? Did the men of the fourteenth century start from first principles regardless of what had been done in the thirteenth? Do we admire their work the less because we can almost trace the current of the thoughts of those who evolved it? Do we sneer at them as imitators and copyists? Could they have done such mighty works if they had refused to profit by the past, and had attempted to evolve cathedrals out of their moral consciousness? To ask these questions is to answer them, and at the same time to answer a great many of the criticisms which are directed against us.

For to compare great things with small, the cases of architecture and of carpets run on all fours. In each there was a great period when the art was living and progressive, and during which great typical examples were evolved, specimens of which still survive, and which are the despair of modern imitators. In each there was a period at which growth was arrested, and in each there has been a revival founded on the past, and in the midst of which we are more or less blindly groping our way towards the formation of what centuries hence will probably be recognised as a distinctive style.

The great sixteenth-century carpets are in their way unapproachable masterpieces, just as the Mediaeval cathedrals are, and in taking them as our exemplars we are in distinguished company. I must admit that in one respect the parallel is not complete, and that the architects have the advantage of us. Fortunately for them buildings are not portable. If they were, and if one may judge from analogy, this country would be as full of Eastern mosques as it now is of Eastern carpets.

There is a strong tendency at the present time to condemn all attempts to evolve ornament on the basis of what has been already done, and to exalt those who are attempting to originate decoration by going direct to nature and conventionalising her forms by methods of their own. I have very great sympathy with their aims, which at one time I fully shared. I remember at that period I looked upon a Louis XVI. scroll as something positively immoral. It would be difficult to withhold one's hearty admiration from the men who are endeavouring to realise such ideals were it not for the feeling which will obtrude itself, that there is a certain amount of insincerity and affectation in their attitude. Those I have in view seem to say to themselves, “Drawing is not our strong point; we find complicated arrangements troublesome, let us therefore devise a method in which drawing is of little importance, and let us create for ourselves a style involving a minimum of labour which shall be founded on nature as seen through our temperament,” and they succeed; but there is one element of their

temperament which they cannot eliminate and which is fatal to their success. They are always self-conscious and seem to say, "Go to, let us be naïve and quaint." They are trying to do of set purpose what the great original workers in decorative art did without thinking much about it. These did not stop to analyse their conceptions and to say, "I must reject this or that, however good it may be, because it is founded on what has been done before." In the modern work a certain *naïveté*, which is one of the greatest charms of all good original conventional ornament, is wanting; and it must be so from the nature of the case. But when in place of this *naïveté* we find an affectation of it, resulting in the production of what one of its practitioners, with commendable frankness, speaking of his own work, calls "crude symbols," we must be pardoned if we cannot quite accept the one as the equivalent of the other.

I cannot too strongly protest against the assumption by this school that what they cannot do ought not to be done. They insist, for instance, on structure showing prominently, and on the necessity for emphasising the repeat. Now it is much easier to make a design showing its framework than one which conceals it. Subtlety means difficulty, and the taking of infinite pains. If a designer finds that he cannot achieve it, well and good. It is very commendable for a man to recognise his own limitations, and to accept them as the bounds of his own efforts; but when he attempts to lay down the same rule for others, and to make his incapacity the measure of their endeavours, one can only think of the tailless fox, and marvel how history repeats itself.

I do not by any means mean to argue that good designs cannot be made in which repetition is insisted upon. What I protest against is the laying down of any rules of this kind whatsoever. The only rules which should be observed are those which naturally assert themselves: those which arise out of the nature of the fabric, and the purpose to which it is applied.

These men are unknowingly setting themselves no less a task than the opposing of a great stream of tendency, of pitting themselves against that law of evolution which governs the operations of the human mind as well as of organic nature, and controls even that wayward thing the artistic temperament, of which apparently it might be said that, like the wind, it "bloweth where it listeth."

Nothing is apparently farther from their thoughts than that the great generalisations of natural science have anything to do with them. But they would, notwithstanding, find it a useful discipline to give a little time to the study of its general principles. They would learn that we are all of us, decorative artists included, the creatures of heredity, modified to a slight extent by our present environment. Evolution has turned us out bipeds, and our wisest course is to make the best use of our legs, instead of trying to grow a pair of wings.

As in nature, so in art, no great achievement has been arrived at *per saltum*. There may be apparent exceptions, like the sports familiar to gardeners, as when a plant which has always borne white flowers suddenly produces a yellow one. But even here there is only a slight modification of what has gone before. And in art, as in nature, everything good and lasting has been founded on the past.

It seems to me that good decorative art must consist of two elements, the sum of the influence of what has been done in the past, plus the new element due to the idiosyncrasy of the artist. The first without the second is dead, the second without the first has life, but it is life striving to release itself from the guiding laws of evolution and heredity, and in the fruitless struggle it only produces abortions and monstrous growths. Suppose that in the organic world these great governing laws should cease to operate, what sort of animal and vegetable organism would be produced? And the same holds good in the world of mind.

I may seem to contradict myself in maintaining, on the one hand, that we are creatures of the past, and on the other that we have power to impress our own idiosyncrasy on our work, but both are true. To borrow an analogy from our physical structure, we have inherited an apparatus admirably suited for walking purposes, but we can deform it by tight boots; and so with our mental equipment. We can either work with nature along the lines we discover by observation of her methods, or we can, to a certain extent, thwart and impede her, with the certain result of crippling our bodies and stunting our minds, or in some cases, it may be, of causing unhealthy abnormal growths.

It is fortunate for designers of this type that their measure of executive power is frequently supplemented by a considerable development of the gift of literary expression. And in addition to their self-advertising solo performances, they are able to command a sympathetic chorus of admiration from their admirers among art critics; so, altogether, the voice of their trumpets is exceeding loud, and the not too discerning host of the Philistines is much impressed thereby. In such work as theirs there is more of the worker's delight in himself than in his work. The object seems not to be so much to

produce a thing of beauty as to cause people to say, "What a very original artist."

It seems to me that this school, when they and their work have receded into the past, will occupy much the same position in relation to art that the Euphuists of the seventeenth century have in literature. Both movements alike will be seen to have their roots in self-consciousness and affectation, and will take their proper place as mere excrescences on the main stem of progress. Or to take an illustration from recent literature, some of the work that is done by the extreme men bears about the same relation to good decoration that Lewis Carroll's "Jabberwock" does to good literature. In both you have invention, originality, freedom from convention, and from the debasing influence of style. Both also appeal to our sense of humour, though in the case of the designers this is quite unintentional, and we are asked to accept their Jabberwocks as serious works of art. When a designer of this type comes in contact with a manufacturer, his soul is moved to indignation if, with the best and most kindly intentions, he is shown specimens of good work as an indication of the line he might usefully follow; and here, by good work I do not mean mere commercial successes, but reproductions or adaptations of old fabrics, which are admitted on all hands to be good, and whose only fault is that they are not new. As, for instance, a manufacturer finds in some old brocade or velvet forms which, when suitably arranged, make a carpet satisfactory in all respects, except that it is not original. He is reproached with this, and admits the justice of the reproach, inasmuch as he would prefer to produce something entirely new, of which he and the designer might share the credit. But any attempt to indicate what is wanted is resented by the designer as an unwarrantable cramping and fettering of his powers. It seems to me, on the other hand, that the reception of such a suggestion in such a spirit indicates an amount of arrogance and self-sufficiency, which would be tolerable only if it were found in conjunction with a complete mastery of the subject and with executive powers of the highest order. If a modern designer can show that in any of his productions he has in any degree, in form and colour, approached the standard set up in the best work of the past, he might reasonably expect a mere manufacturer to give him a free hand, and to accept, with reverent gratitude, what he may be pleased to produce. But until he has so made good his claims, he can scarcely be surprised if his crude symbols are not accepted at his own valuation; nor must he expect the manufacturer to acquiesce in the calm assumption that he is a mere master weaver, bound to defer to the designer's amateurish notions of what a carpet should be, for amateurism is writ large over all the productions of the extreme men of this school.

We do not want dictation, and I have given, and shall give, some reasons why we should not be expected to submit to it. Some of us have devoted many years to the study of the subject, and have brought to bear upon it such small measure of artistic training as we have been able to acquire. Can it be expected that we shall meekly accept the crude notions of the *dilettanti* dabblers who conceive themselves qualified to teach us? Their pretensions remind us of Triplet in Charles Reade's "Peg Woffington":—"Triplet was teaching the butcher's son how to plant onions. He had never seen onions planted, but he was one of those people who are always ready to teach anything to anybody." The assumption that the designer who has made no special study of the requirements of a particular fabric should have a free hand whenever he chooses to turn his attention to it, is so ridiculous that it need only be stated to expose its absurdity. It is as though a sculptor should expect a commission for a picture without having shown the slightest capacity for dealing with colour. But we find the doctrine that architecture is the foundation of all the arts has taken such hold of some of its practitioners, that they consider themselves qualified to make designs, not only for houses, but for all things that are therein—an assumption which, in the case of carpets, has scarcely been justified by results.

It may be thought that I am going out of my way to attack this new English school of designers. I have said that I sympathise with their aims. I share their desire to escape from the bondage of tradition, and to create something which is their very own. But I think that, like other reformers in the past, in rebelling against authority they have gone to the other extreme, and are therefore certain to defeat their own ends. I should like to see their enthusiasm for art and their undoubted inventive genius directed into channels where they could do work of permanent value. And I deeply regret that my own special craft must suffer from the lack of their co-operation, which would otherwise be gladly sought, so long as they maintain their present uncompromising attitude. I am convinced that their theories and their practice are fatal to the advance which I desire to see. Through their close relations with a certain section of the press they exercise an influence which I think a harmful one, and I fear that the glamour thus thrown round them and their works may result in the production of a host of feeble imitators, a result which I am sure they will agree with me is too awful to contemplate.

On one occasion the late Sir Philip Owen undertook to tell me how manufacturers should avail themselves of the advantages offered by the training schools and museum at South Kensington. He said, "You should take one of the young men who has passed through the schools with distinction, pay him a good salary, leave him entirely free and unfettered, let him remain here drawing inspiration from the wealth of material here accumulated, and take what he gives you. In this way only will you get freshness and originality."

Now this, which may, I suppose, be taken as the official view of the relations which should subsist between South Kensington and manufacturers, differs from that of what I have called the new English school, inasmuch as the latter eschews the idea of profiting by the work of the past, but they are at one in proposing to give the manufacturer no voice in the matter. I did not act upon the advice for several reasons. First, experience tells me that it is utter waste of time for any one who has not had a thorough technical training to do work which shall be practically useful, and a manufacturer cannot be expected to pay for failures due to this cause, though, as a matter of fact, commissions are not unfrequently given to promising young designers, the results of which are paid for and then put in the fire. Then if it be a question of imbibing inspiration from the great works of the past, a manufacturer is much more likely to get good results from a designer who has been trained in his own methods, and knows exactly how to select and adapt to practical purposes, than from a young beginner, however gifted he may be.

I cannot withhold my conviction that, so far as carpets are concerned, our art-training schools are not sufficiently in touch with manufacturers, to their mutual disadvantage. And I think this may to some extent arise from the frame of mind to which I have referred. Manufacturers are not invited in any way to co-operate, their advice is not sought. That their ideas upon the artistic side of designing should be ignored is not so much to be wondered at, but why their help has not been sought in technical matters is inexplicable. The result is seen in the carpet designs at the annual exhibition of students' work. I have carefully examined these from time to time, and found that not one of those shown last year was free from technical faults, most of them so radical as to make the designs quite useless.

(To be continued.)

TESSERÆ.

Opus Alexandrinum.

WE may take it that, as a general rule, the floors used by the ancients presented a general mass of pleasing ornamentation, with just so much colouring as would serve as a sort of base for any decoration on the walls, but without being at all obtrusive in themselves. With the architects of the early Christian times, those to whom we owe the great basilican churches of Rome, Ravenna, &c., we get an altogether different class of paving, the Alexandrine. This seems to derive its name both from the Emperor (Alexander) who introduced it into Rome in the third century, and from the place whence he derived it, viz. Alexandria. It had been no doubt used in the East long before by the Pagans, but it is so commonly found in the Christian churches that it is almost identified with them. We have a very early example of this in the famous Byzantine church of St. Vitale, at Ravenna, and several others, though in fragments, in the various churches in Constantinople. One of the most characteristic specimens is from St. Lorenzo Fuori. This seems to be formed of circular slabs of marble porphyry and other coloured marbles or granites, taken as centres, with patterns in small mosaics taken round these in geometrical forms and imbedded on slabs of marble. The large centre circles are very irregular in outline, but the sweeping lines of the small mosaics round them are truly struck, so that the borders are of very irregular width. In this case and in that of all (or nearly so) the Alexandrine mosaics, the whole of the materials are of a kind to bear a fine polish. The green is of a verde antique, the red of porphyry, and the ground of white marble, the whole undoubtedly of a much more gorgeous character than that of the ancient Roman pavement. But we must remember that the whole colouring was that of the actual material used. There was nothing but nature in the decoration, and this is never gaudy. Examine a piece of verde antique, a deep red porphyry, and it will be found that it is little more than of a rich neutral tint—nothing of the light green, blue and red of an artificially made tile. Then the marble ground, white enough when first laid, became toned down to a rich stone colour by the damp which rose to it from the earth on which it lay; and the whole series of patterns was lowered in brilliancy in the same way as the ancient Roman were, though not to the same extent, by each of the pieces which composed it being bedded in a brown cement, with joints which were often very wide and carelessly made. So

that when these pavements had the gloss slightly taken off them by time and wear, they must have formed a very beautiful pavement of rich, but subdued colouring, without a single piece of positive colour about them. In their present state nothing can be more effective. And we see their effect as well probably as when they were new, because the colouring to the walls and ceilings, then fresh, is now subdued as the pavements are. It is scarcely necessary to mention that there are a few specimens of this work in England, as at Westminster Abbey and at Canterbury. But they are on too small a scale to give a good idea of their general effect when used throughout the area of a large church. If we come down to later times amongst the works of the Mediæval architects here and abroad, we get the same succession of subdued half tints, however deep in tone they may be.

Ancient Irish Churches.

In nothing was the Irish Church so indebted to the stranger as in architecture. The buildings in the service of religion before the invasion of the English were of a very unpretending character in Ireland. The door was generally to the west; the windows were narrow, splayed inwardly and always unglazed, because glass for glazing purposes was almost unknown. The churches were small in dimensions, seldom did they reach 60 feet in length and never more. Poverty of spirit was displayed even in the service of God. The Irish churches were nearly all wooden structures. Dr. Lanigan makes very light of this matter and says:—"In building these churches of wood the Irish had no peculiar motive imaginable except that they were very little in the habit of erecting any sort of edifices of stone or other materials. Accordingly nothing can be more ludicrous than the assertion of a silly, presuming author that the doctrine and discipline of the Irish Church were averse to stone fabrics. Even before the twelfth century some stone churches had been erected in Ireland, although it was not until that period that this fashion was introduced into some of the northern parts." The learned Doctor makes the very natural remark that it cannot be expected there should be any remains of such wooden structures at present. Some idea may be formed of them by those who have seen the wooden churches thrown up by the Free Church of Scotland at the time of the disruption. In the Irish churches, no doubt, the workmanship was much more rough, but some of them were so ornamented as to present a splendid appearance. The finest perhaps of these was at Kildare, founded and richly endowed by St. Bridget. As described by Cogitosus in the early part of the ninth century, it was large and lofty and adorned with paintings. It was composed entirely of wood, and cruciform on plan. At the head of the cross was placed the altar, and this part was entered by a door at each end. The right door was for the bishop and those who were to assist in the service; the left was for the abbess and the nuns. The body of the church was divided into two equal parts by a wooden partition, in order to separate the sexes, who were not allowed to mix in any of the Irish churches. For the men there was a large door not in the front, but in the side, and for the women a corresponding door at the opposite side. As this was one of the grandest of the churches, a sort of cathedral, which vied with Armagh, we may easily infer the style of those which existed in inferior places.

Modern Art.

One marked characteristic of modern painting is its accurate study of nature and tendency to detail. The age, whether we turn to science, commerce or legislation, is one of detail, and art partakes of the general bias. This is specially seen in landscape by the close study of nature throughout and in the minute realisation of foreground objects. This careful elaboration may likewise arise, in some measure, from the lack of strong impulsive genius. Men in whom genius is paramount are frequently impatient of close study; they are not eminently learned; the one necessity of their nature is an outpouring expression. Now the absence of this overflowing impulse is especially conspicuous in extant art. It is, perhaps, a misfortune, resulting from position, that makes modern artists copyists and compilers. The first artist could not possibly copy or compile, the last can scarcely help it. The first man is original, the last learned. Still even the latest manifestation of genius, true to its inherent constitution, must create an originality of its own. Painting, like architecture, failing in original creative capacity, falls back upon greater accuracy and truth than was attainable in earlier ages. But if living art can show no examples of giant greatness, at least the strength which does exist is widely diffused. The arts have infused themselves into manufactures, and, in return, the spirit of manufacture has invaded art. Ancient schools and epochs originated in and centred around men of genius; it is now sought to organise such periods through associations called "academies." Nevertheless, let us rejoice that we live not in utter darkness; in the absence of suns, satellites, with borrowed light, may cheer our way.

Roman Architecture.

When the best period of an art is over, and a degenerated and imitative one succeeds, it is to be expected that the latter should exhibit a non-comprehension of some, and an extravagant use of other, of the means employed to affect the imagination in the former and purer time. This was the case with Roman architecture. We may discover in it a lively appreciation of the expressional effect of some few Greek details, and a tolerable comprehension of the source of that effect; but the Roman architects had no knowledge or feeling of the severity with which the various elements of the Greek art were subordinated to the perfect utterance by the whole of the language which was spoken more or less plainly by every part. Isolated details, therefore, acquired an independent importance; the colonnade, which in Greek architecture had no significance without reference to the supported entablature, was raised, as it were, for admiration on a series of pedestals; single shafts rose beneath nothing in the places of public concourse; and attempts, entirely and necessarily abortive, were made to reconcile and harmonise certain of the Greek details with the new and contradictory element of the semicircular arch. Circular form was diligently sought for. The Doric shaft became a plain cylinder; the outlines of mouldings, in Greek architecture conic sections, became segments of circles; the dome rose behind the pediment, the horizontal entablature was at last wholly relinquished, and the arch sprang from column to column, bearing with it the entablature curved, and in this condition of impotence and inconsistency the architecture of pagan Rome was transplanted to Byzantium.

Eighteenth-Century Wall-Painting.

Wall-painting professed to be the handmaid of architecture; when the mason and carpenter and plasterer had done their work, its professors made their appearance and covered walls and ceilings with mobs of the old divinities, nymphs who represented cities, crowned beldames for nations, and figures ready ticketed and labelled answering to the names of virtues. The national love of subjecting all works to a measure-and-value price, which had been disused while art followed nature and dealt in sentiment, was again revived, that these cold mechanical productions might be paid for in the spirit which conceived them. The chief apostles of this dark faith were two foreigners and one Englishman, Verrio, Laguerre and Sir James Thornhill. Rubens, indeed, and others had deviated from nature into this desert track, only to return again to human feelings with a heartier relish. But Thornhill and his companions never deviated into nature. The shepherdesses of Sir Peter Lely were loose in their attire, loose in their looks, and trailed their embroidered robes among the thorns and brambles of their pastoral scenes in a way which made the staid dames of the puritans blush and look aside. But the mystic nymphs of Thornhill or Laguerre, though evidently spreading out all their beauties and making the most of their charms, could never move the nerves of a stoic. It is in vain that a goddess tumbles naked through a whole quarter of the sky. It is astonishing how much and how long these works were admired, and with what ardour men of education and talent praised them.

Pericles and Athens.

Pericles was not less ambitious for the greatness of Athens than the most daring visionaries; but he better understood on what foundations it should be built. The objects of Pericles were to strengthen the possessions already acquired, to confine the Athenian energies within the frontiers of Greece, and to curb, as might better be done by peace than war, the Peloponnesian forces to their own rocky barriers. The means by which he sought to attain these objects were, first, by a maritime force; secondly, by that inert and silent power which springs as it were from the moral dignity and renown of a nation—whatever, in this latter respect, could make Athens illustrious made Athens formidable. Then rapidly progressed those glorious fabrics which seemed, as Plutarch gracefully expresses it, endowed with the bloom of a perennial youth. Still the houses of private citizens remained simple and unadorned; still were the streets narrow and irregular; and even centuries afterwards a stranger entering Athens would not at first have recognised the claims of the mistress of Grecian art. But to the homeliness of her common thoroughfares and private mansions, the magnificence of her public edifices now made a dazzling contrast. The Acropolis that towered above the homes and thoroughfares of men—a spot too sacred for human habitation—became, to use a proverbial phrase, “a City of the Gods.” The citizen was everywhere to be reminded of the majesty of the State—his patriotism was to be increased by the pride in her beauty—his taste to be elevated by the spectacle of her splendour. Thus flocked to Athens all who throughout Greece were eminent in art. Sculptors and architects vied with each other in adorning the young Empress of the Seas—“as a vain woman decked out with jewels,” was the sarcastic reproach of the allies. Then rose the masterpieces of Phidias, of Callicrates, of Mnesicles, which even either in their broken remains or in the feeble copies of

imitators less inspired, still command so intense a wonder and furnish models so immortal. And if, so to speak, their bones and relics excite our awe and envy as testifying of a lovelier and grander race which the deluge of time has swept away, what in that day must have been their brilliant effects—unmutilated in their fair proportions—fresh in all their lineaments and hues? For their beauty was not limited to the symmetry of arch and column, nor their materials confined to the marbles of Pentelicus and Paros. Even the exterior of the temples glowed with the richest harmony of colours and was decorated with the purest gold; an atmosphere peculiarly favourable both to the display and the preservation of art permitted to external pediments and friezes all the minuteness of ornament, all the brilliancy of colours; such as in the interior of Italian churches may yet be seen—vitiating in the last by a gaudy and barbarous taste. Nor did the Athenians spare any cost upon the works that were, like the tombs and tripods of their heroes, to be the monuments of a nation to distant ages and to transmit the most irrefragable proof “that the power of ancient Greece was not an idle legend.” The whole democracy were animated with the passion of Pericles, and when Phidias recommended marble as a cheaper material than ivory for the great statue of Minerva, it was for that reason that ivory was preferred by the unanimous voice of the assembly. Thus, whether it were extravagance or magnificence, the blame in one case, the admiration in another, rests not more with the minister than the populace. It was, indeed, the great characteristic of those works that they were entirely the creations of the people: without the people, Pericles could not have built a temple or engaged a sculptor. The miracles of that day resulted from the enthusiasm of a population yet young—full of the first ardour for the beautiful—dedicating to the State, as to a mistress, the trophies honourably won or the treasures injuriously extorted, and uniting the resources of a nation with the energy of an individual, because the toil, the cost, were borne by those who succeeded to the enjoyment and arrogated the glory.

Gothic Column.

The Gothic architect, after he had once perceived the kind of effect which it was desirable to substitute for the Lombard expression (the Lombard construction having been discarded), found, almost ready-made to his hand, one of the most important of the numerous means of producing it, namely, the Lombard ornamental column, with its base and capital, which in various ways expressed a total independence of constructive origin. There was, however, this difference between the Lombard shaft and the Gothic shaft—that the first was constructively superfluous, and expressed as much; whereas the last had really to take a primary part—to bear burdens, and yet appear to do nothing of the sort, the burden and bearing members being alike transformed into portions of the great vertical stream of piers, pointed arches, groined vaults and vaulting shafts. The simplest way of obtaining this effect was to leave out base and capital altogether. It took some time, however, for architects who had always regarded a capital and a base as the natural extremities of a shaft to get rid of the tradition, and when at last they seem to have done so, it was found that a base of some sort was essential to safe construction, and that there were serious artistical objections to dispensing altogether with the capital. When capitals were totally omitted, as sometimes was the case in splendid examples—Cologne among others—the eye became sensible of an unpleasant dubiousness as to the point from which the arch sprang, and when the moulded or many-shafted pier was the stem from which arose a system of still more numerous divergent ribs and mouldings, the capital was needed to cover the junction of the two systems, its omission necessitating the very disagreeable alternative of the “discontinuous impost.” Elaborate devices were therefore invented for denying and, as far as possible, reversing in their visual effects the nature of bases and capitals as constructive members. Mr. Ruskin condemns a large class of Gothic capitals as “unnecessary and ridiculous” because they have “no bearing power.” Now we hold that this expressed absence of any increase of power at the point of the capital is the only condition under which capitals could have been admitted into Gothic architecture, and that they are neither “unnecessary” nor “ridiculous” because they perform what we have seen to be the important function of marking the termination of the shaft or pier and the commencement of the arch. Another, and a very good reason for the existence of capitals in Gothic architecture is one and the same with that which constitutes the merit of the horizontal channels under the Doric ovolo, namely, that they really add to the ascendant vigour of the members on which they occur by opposing to that vigour an obstacle to be conquered. Mr. Freeman, whose remarks on some of the means of producing the effect of aspiration in Gothic architecture are particularly valuable, rightly says, “When there is no strife there is no victory: the vertical line cannot be called predominant unless the horizontal exist in a visible condition of subjection and inferiority.”

NOTES AND COMMENTS.

SOME years ago Mr. GEORGE MURRAY, of the Museum of Natural History, gave an account in *The Architect* of the *Merulius lacrymans*, the organism which is the cause of dry-rot. The French have of late taken to study the subject, and the *Temps* has had several communications on it. M. CRIÉ, a professor of Rennes, says that for years the *Merulius lacrymans* has been his favourite study, and he has collected evidence of a great many accidents caused by its presence in scaffolding and timbers employed in construction. He believes that the danger arises from a destruction of the woody elements, and that it is absurd to suppose the exterior of a piece of wood always appears superficially sound while the interior is decomposed. He also says it is an error to believe that the danger arises only in damp or imperfectly-ventilated places. Timber which presents parasitic alterations and lesions will be found in dry positions. M. MANGIN, of Douai, is of opinion that the fungi can be destroyed by applying sulphuric acid. He mentions a case of a house where dry-rot appeared forty-five years ago, and a floor was destroyed. The rest of the wood was washed with the acid, and since no trace of the fungus is perceptible. He believes that if the acid were applied as soon as the wood-work was complete, there would be no chance for the *Merulius*. Mr. MURRAY found that paraffin was the most efficacious destructive.

THE PICTET family is closely associated with the intellectual development of Geneva. Sir J. D. FORBES says that towards the close of the last century the city had nearly reached the zenith of its reputation as a nursery of the sciences, for "the most eminent and independent of its citizens were proud of being also amongst its instructors, and the office of professor was then, as it still is, considered one of the most honourable in the State." At that period MARC-AUGUSTE PICTET was, according to FORBES, known and esteemed by the learned throughout Europe. He was a great authority on heat, and among his good deeds was the establishment of meteorological observations at the convent of the Great St. Bernard, which are still continued, and are among the most important that have been made. M. RAOUL PICTET, who is one of the most eminent of the present citizens of Geneva, has resolved to uphold the zeal of his family for science in the worthiest manner. In connection with the exhibition which is to be held in 1896 he proposes to set up what he simply calls "un établissement scientifique," but which will be a palace dedicated to the sciences of which Geneva was the nursery. In it the applications of science will be exemplified on the largest scale, and one of the lecture-rooms will accommodate 350 people. As is only natural, there will be as complete a collection of apparatus connected with thermodynamics as can be obtained, in order to explain the developments of that branch of science since 1791, when PICTET published the important work which he modestly called "Essai sur le Feu." As a further experiment on a large scale, M. RAOUL PICTET intends to show what can be done in reducing temperature by the construction of a circular gallery and restaurant, which will remain uniformly cool and refreshing throughout every summer. This work must recall what was anticipated by PIERRE PRÉVOST when dealing with the "Movable Equilibrium of Heat." An Institut Raoul Pictet, which is also to be set up, will be a further addition to the scientific resources of Geneva.

WHILE the staff and students of the English school at Athens are pottering about barren spots and performing feats of easy measuring, the French and Germans are increasing their triumphs as explorers. According to the last account the French have discovered the caryatids and frieze of the Temple of Apollo at Delphi, and expectation is on tip-toe about the treasures that will follow. It should be remembered that not only the Greeks, but Phrygians, Lydians, Persians, Assyrians, Phœnicians, Italians and the Hyperboreans themselves, says LUCIAN, sent offerings to Delphi. The temple was undoubtedly plundered at least eleven times before NERO carried off a hundred statues from

it, and other Romans and Goths were afterwards busy in the spoliation of a sanctuary that had acquired an universal reputation. But the eagerness of the vandals to seize their prey may have caused little treasures to be trodden into the soil, which now would be more precious than jewels. Nor can we suppose that all parts of the temple were ground into rubbish. That the site of the building was for ages covered with humble huts is not to be deplored, for the place became in consequence too mean to excite the cupidity of later investigators. Besides the temple, there is much else in Delphi which is likely to reward exploration if properly conducted.

A CONFERENCE of representatives of Metropolitan local authorities and others was held at the Vestry Hall, Paddington, last week. After hearing an explanation by Mr. H. H. COLLINS of the general character of the London Streets and Buildings Bill, the following resolution was passed, with only one dissident:—"That this conference, whilst fully admitting the expediency and justice of dealing with land, and regulating the construction or reconstruction of buildings thereon in such a manner as may be conducive to the public interest, considers that many of the clauses in the Bill are neither just nor expedient, inasmuch as they would tend to check rebuilding and injuriously retard the development of freehold and leasehold estate; and, further, that compensation should be given where property is taken under compulsion."

EXPERIENCE shows that it is most difficult to employ landscapes in wall-decoration, especially when figure subjects are to be seen in the same room or building. French artists endeavour to attain the end by the introduction of conventional forms in order to suggest that the picture is not an ordinary landscape. M. PAUL ROBERT has solved the problem in a novel way. In 1886 he was offered a commission for three immense panels which were to adorn the staircase of the Musée des Beaux-Arts in Neuchâtel. M. ROBERT wished to represent the district as nature had created it, and at the same time to express the desire of the people for the symbolising of their loyalty to Protestantism. He has therefore surrounded the landscape scenes with figures which represent all the virtues, and are as expressive as any to be seen in the churches of the Catholic cantons. The three panels have required the unremitting toil of eight years, and are probably the most remarkable of the modern examples of wall-decoration.

AMERICA is not the only country where custom-house officers become a torment to artists. The Italians appear to have resolved that they will outdo all the rest of the world in obstructive regulations. The majority of the pictures sent back from the Chicago exhibition appear to have gone through adventures by land and sea before they reached their owners. The adventures of Italian works are not yet ended. Those which belonged to artists in Rome did not arrive in Genoa until February 24. It required no less than forty days before they could overcome the difficulties of the way between Genoa and Rome. Having reached the capital, the pictures are still kept in durance because some formality was not gone through in Chicago. When natives are treated so harshly, English travellers in Italy need not complain of their experience.

It is proposed to ask a vote of 4,000*l.* from the French Chambers in order to pay for the expenses connected with the competition for designs for the international exhibition of 1900. The architects will be allowed to deal with the existing buildings on the Champs de Mars according to their discretion. There will be no stipulation in the conditions about the retention of any of the galleries remaining from the exhibition of 1889. If the money is granted no time will be lost before arranging the competition, in order that a design may be selected before the close of the year. It is proposed to adopt a new system of arrangement, and instead of exhibiting machines apart, they are to be introduced in the vicinity of the objects which they produce.

ADELPHI BANK, LIVERPOOL—THE PORCH.

NEW OFFICES, "NORTHERN DAILY TELEGRAPH," RAILWAY ROAD, BLACKBURN.

THIS building, which we illustrate in our present issue, has just been completed for the North-Western Printing and Publishing Company, Limited. It occupies a most convenient and commanding site close to the principal entrance to the railway station. The buildings are admirably arranged for the purposes for which they are erected. On the ground floor very commodious accommodation is provided in the shape of a large general office for the transaction of public business, private offices for the managerial, editorial and reporting staff, with cloak-rooms and all other conveniences in connection therewith. The main entrance is at the corner of the building, as shown in the drawing. On the same floor, and approached from the side street, is a very large machine-room and rooms for the receiving and despatching of parcels, &c. Leading from the machine-room is a convenient office for the supply of papers to the news-agents and news-boys' rooms; these rooms have separate entrances from the back street. The first floor is occupied by a very commodious compo-room, stereo-room, office, and other conveniences. The basement is very extensive, and contains large paper and other stores, damping-room, boiler-house, fan-room, dynamo-room, &c. This floor has separate entrances from the back roads. The elevations are of Accrington bricks, with buff terra-cotta dressings from Burmantofts, Leeds. The dome of the tower is covered with copper. The building is fireproof, and the construction throughout is of the best possible character. The machinery and other fittings are of the most modern and approved make. The heating and ventilation scheme has been carried out by the Sturtevant Engineering Company, Queen Victoria Street, London, and the electric-lighting installation by Mr. THOMAS BARTON, of Blackburn. The contractors for the building are Messrs. JOHN HIGHTON & SON, Witton, near Blackburn, and the whole of the works throughout have been carried out from the designs and under the superintendence of Messrs. STONES & GRADWELL, architects, Richmond Terrace, Blackburn. Mr. EDWARD LEWTAS, of Blackburn, was clerk of works. The total cost is about 20,000*l*.

ST. MARY'S, KEMSING—RESTORATION OF ROOD-SCREEN.

THIS is a most interesting piece of old work, the detail being very refined, and the carving most delicate in treatment and executed in a masterly manner. It is without doubt one of the finest examples of this date of work to be found. The lower portion was in a fair state of preservation, but in the upper part much of the tracery had disappeared. There were a few perfect pieces remaining, which left no doubt as to the original design. The groining and rood-loft over had entirely disappeared. Traces of coloured decoration are still remaining, but are almost entirely obliterated.

The restoration has been most faithfully carried out by Mr. UNSWORTH, architect, and the work executed by Mr. HITCH, sculptor.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

AN ordinary meeting of the Institute of Architects was held on Monday evening, Mr. J. Macvicar Anderson, president, in the chair.

The decease was announced of Colonel Haywood, F.R.I.B.A.

The business of the meeting was the reading of papers in connection with the art standing committee, on the subject of furniture in conjunction with architecture, under the title of

Furniture: Domestic and Ecclesiastical.

Mr. JOHN BELCHER read the first paper, and remarked that the subject selected was one that should occupy the attention of architects. What dress was to individuals as indication of position and character, so was furniture in relation to buildings. In tracing the first origin of furniture, he dated it from migratory races—the chest in which they carried about their possessions, and which served as table, seat, &c., being the progenitor of the press, cabinet, dresser or sideboard, to which legs were added when locomotion was no longer the custom:

With fixed and permanent abodes came in the interlacing of furniture with buildings as fittings. For transitory purposes furniture should be selected for general utility, adapted in kind, size and scale to its surroundings, and the movable objects should bear proper relation to the fittings; absence of proportion and scale would reduce and spoil the apparent size of a room. The selection of disproportionate furniture was a common error into which inexperienced persons fell who purchased ready-made furniture of a sloppy description. Among the best work of the past Mr. Belcher instanced work in Italy and the Netherlands, then that of France, and later, in the eighteenth century, that of Chippendale, Heppelwhite and Sheraton, combining a maximum of strength with a minimum of material in elegant forms. In all periods there had been recognised formulæ which characterised good work, and these were described. Also in all good work form and construction were the result of long tradition, and characterised by directness and fitness of purpose. Furniture might be, no doubt, decorative, but should not be used as a means of decoration, which would be an abuse of purpose. The work should be the product of thought and time, for smoothness and polish of surface would not supply the defects of hurried work and absence of thought.

Mr. C. F. A. VOYSEY, on the subject of domestic furniture, alluded to the prevalence of merely depending on upholsterers for furniture; display, gilding and veneer there was, but simplicity, repose, harmony and dignity were wanting. Much of this was due to the spirit of revivalism. Mankind was still very much in a monkey stage, mocking and mimicking old and new work, good and bad. Commercialism also offered its rewards all round to the best mimics. Many, however, though not artistically trained, happily had revolted against the tawdry pretentiousness of the bulk of modern furniture, and encouraged the reproduction of old and simple furniture that had been designed with intelligence to meet human needs, and were not the outcome of any spirit of revivalism. It was clear, therefore, there must be a logical basis for design of furniture. But all must be impressed with the present utter want of harmony between furniture and architecture—except in jerry buildings. Still, he thought, there was hope, for there were signs of change in a right direction and a widespread feeling that simplicity would lead to truer richness. The carver, metal-worker, &c., should exercise restraint. Concentration of ornament to hide cheap construction, bad workmanship and material, must be avoided. Elaboration covered a multitude of sins, and he would add virtues also, as was apparent in the deadly dullness of the design of the bulk of modern inlay, which destroyed the beauty of the wood into which it was put. The paper concluded by condemning all in the way of mechanical reproductions, and advocated the cultivation of creative faculty. However faulty the work of the designers, if only conscientious it would be interesting, and not as now a funeral procession of dead styles.

Mr. ALDAM HEATON read a paper on "The Theory of Hangings." He observed at the outset that he should confine himself entirely to the practical side of the question. The word "hangings" came, he believed, from the Mediæval house, with its tapestry hangings, and had got transferred to pasting on walls paper that did not hang. Without entering on the subject of tapestry, Mr. Heaton gave an exhaustive description of fabric for hangings, &c. These as a rule should be fairly dense in texture, and in their nature suggestive of warmth and protection; they must be firm and not flaccid, and must go into good folds, the character of the folds being a matter of primary importance. The use of cotton fabrics he condemned, for cotton deteriorated most fabrics utterly, and made one suspicious of the rest. Wool he placed first in importance, including also goat's and camel's hair, the woollen process producing softness and sense of warmth, and the worsted process firmness, crispness and springiness. Silk came next, but was used in general only as a facing, being backed up by other material. Incidentally it was mentioned that so fine was the filament that a thread reaching from London to Edinburgh could be sent by post for 2*d*. After cotton came linen and jute, the latter producing a fairly respectable velvet. Dyes faded in cotton, except in the case of Turkey red and indigo blue, far more quickly than was the case with silk or wool. Serges and flannelling fabrics gathered dirt more quickly and looked shabby sooner than worsted and wool. For purposes of utility jute was probably a more useful fibre than cotton. Tapestry, embroidery and crewel-work were out of reach of most on account of cost, and here damask weaving came to the rescue of the multitude, but for sake of cheapness there were temptations to swamp it with cotton. Mr. Heaton then proceeded to speak of velvet, praising the old examples, and condemning what is now fashionable and known as plushett, though German worsted velvet with admixture of goat's hair was a useful and beautiful fabric. Proceeding to speak of chintzes,

Mr. W. WOODWARD, rising to order, asked what the subject had to do with architecture?

The PRESIDENT replied the subject before them was furniture.

In concluding his remarks, Mr. Heaton gave the following lists under headings good and bad of available drapery materials in order of merit and demerit, viz. good : old tapestry, twills, satins, &c., made from long wool or goat's hair, woollen cloth, silk fabrics if firm, oriental tent coverings, velvet of wool and mohair, camlet and moreen, and woollen serge if on a worsted warp ; bad : cotton velvet, low art serge on cotton warp, soft cotton fabrics and silk plush. The paper then finished with a reference to church hangings.

Mr. W. D. CARÖE, on the subject of church furniture, remarked that many churches in this country were not worthy of their purpose and especially were shoddy in respect of furniture. The architects of the churches ought to have been consulted as to the furniture and fittings of the churches. The architect too often was not consulted in these matters, for instance as to hangings, brasswork, embroideries, &c., and worst of all not consulted when an organ was to be introduced into an old or a new church. Mr. Caröe entirely condemned one specialty of pseudo-Gothic, viz. pitch-pine. If economy demanded its use it should be untouched and unvarnished, and thus, its grossness of texture being toned down, in a few years would be unnoticed. The prevalence of the use of pitch-pine was a curious problem. Some doubted if an edifice could claim to be Gothic without. He, however, would do without it or use it according to his rule ; if it must be varnished, he would say stain it. Early English and geometrical woodwork only seemed worth study from an archaeological point of view, modern designs in these styles being general failures. Nothing, however, to his mind, was more harmonious and beautiful than much of the German, French and English work in which Renaissance detail was grafted on Gothic ideas, though Sir Frederick Leighton had condemned the lack of restraint to be found in much of the later German woodwork. The *cinqe cento* and later woodwork of Italian churches had much to tell of perfect harmony with Gothic forms as seen in modern designs. There was also a field for study in French and Flemish work of the sixteenth and seventeenth centuries. Mr. Caröe concluded his paper by referring to the responsibilities and opportunities of the modern organ builder as to the external appearance and fitness of their work. It was no exaggeration to say that when let loose in a church the organ builder, speaking generically, was the veritable bull in a china shop.

Mr. ALMA-TADEMA proposed a vote of thanks to the authors of the various papers. Some one, he said, had told him not to spend so much time in putting cabbages and furniture in his pictures. He had not, however, changed his ways. To live in houses with bare walls would not do. It was necessary to have seats to sit on, tables at which to eat, various articles in which to put things away in. He would not be too hard on any one because he preferred one particular style to another. Any style he would allow so long as the application was suitable to our actual wants. There was no new form to be invented, though it could be suggested. The present period of civilisation embraced all periods of the past. Every one was free to think as he liked, and there was certainly a great diversity of thought. Some thirty years ago a friend of his had called archaeology the handmaiden of science, and if he might say so, it was also the handmaiden of art. Speaking historically of furniture, he said the most ancient seat we knew was the Egyptian—hollow, extremely comfortable to sit in and very low. The Greeks and Babylonians had a higher and a square seat. From the Romans Mr. Tadema adverted to the Americans, and then came to our seats of the present day. He praised the Chippendale period as one of the finest in regard of furniture. It must have been a clever architect to have done so well, or if he was an upholsterer he had shown himself to be an architect. Architects should study how to give us comfort in houses, churches, &c.

Lord EGERTON OF TATTON seconded the vote of thanks. He said he had had opportunities of seeing furniture in most parts of the world and could confirm what Mr. Alma-Tadema had said, that some of the oldest seats were the most comfortable. He had sat in the marble seat in the theatre of Athens, on which was inscribed the name of the ancient high priest. He thought there was much to be learnt from the ancients in regard of comfort in furniture. In the present day there was the custom of imitating every kind of furniture, and the latest craze was Japanese work ; excellent as Japanese work was, the beautiful examples of furniture abroad should not be neglected, especially the work in Italy. The stalls and fittings of choirs and churches in Italy he believed were more worthy of study than in any other country. The Italians were doing a good work in publishing monthly details of all the best furniture and fittings. The cost was only two or three shillings, and it included full-sized working drawings, plates, illustrations, &c.

Mr. L. KNOWLES, M.P. for West Salford, considered that rectors should not have the power over churches that they possessed. What made matters worse, the rector had to consult the rectorial sisters, aunts, &c. A reredos would be handed over to the village monumental man, the roof to the

village carpenter, and all the bad work would be credited to an architect.

Mr. W. WOODWARD, speaking purely from the architectural point of view, said he would distinguish between the architectural finish of a house and its furniture.

[A person present, whose name did not transpire, during the course of Mr. Woodward's remarks rose to order, and asked what those remarks had to do with furniture. No reply being made, Mr. Woodward continued, and, on the same person rising again to order, the President gave his opinion that Mr. Woodward was not out of order.]

Mr. WOODWARD contended that architects could not do justice to clients if they were to undertake to design chairs, wall-papers, &c. He had an easy chair he sat in all day, but it had not been designed by an architect. He praised the designs of Mr. A. Welby Pugin, which were exhibited.

Mr. J. R. CLAYTON referred to his personal friendship with Mr. Pugin, who designed with great rapidity and in a singularly condensed way.

Mr. J. D. CRACE also referred to the excellence of Mr. Pugin's drawings.

Mr. W. AUMONIER, as an example of what should not be followed, referred to the crude designs shown at the last Arts and Crafts Exhibition, and deprecated any falling back on the babyhood of art.

The PRESIDENT, in putting the vote of thanks to the meeting, coupled with the names of the readers of the papers those who had lent drawings, fabrics, metalwork, &c., that night for exhibition, mentioning among other names those of Mr. Pearson, Mr. Norman Shaw, Mr. W. K. Shirley, Mr. James Brooks, Mr. Crace, the South Kensington authorities, &c.

The vote of thanks was passed by acclamation. Mr. John Belcher replied in acknowledgment, and the meeting was adjourned.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE Peeblesshire residence of Sir Charles Tennant, known as The Glen, was visited on Saturday by the members of the Edinburgh Architectural Association. The mansion-house is in the valley of the Quair, the nearest railway station being at Innerleithen—Scott's St. Ronan's Well—and the five miles drive on by Traquair village and the old parish church, and skirting the hill with "The bush aboon Traquair," is an exceedingly pleasant one. The estate of The Glen stretches along the Quair valley for miles, and the house with its hilly environment and rugged cast of scenery might well call up the memories of the Highlands. In 1852 the estate came into the present proprietor's hands for about 33,000*l.* At that time an old mansion-house stood near the site of the edifice of to-day, and the land afforded a hard struggle for existence to some fifty families. Sir Charles, then Mr. Tennant, besides erecting a handsome residence, spent large sums of money in laying out the extensive grounds, and now from 150 to 200 families are attached to The Glen. Skilful management and liberal expenditure have made it one of the finest residential estates in Scotland. The major part of the present mansion-house was erected in 1854 from plans by the late David Bryce, architect, Edinburgh, and eighteen years later it was enlarged from designs by Mr. John Bryce. It is a stately Scottish baronial edifice, built from Swinton stone, and very elaborately decorated. With its towers and turrets, crow-stepped gables and quaint figures, the structure is a handsome pile, and has well earned the admiration of the many tourists who visit The Glen. Indoors comfort has been especially studied, and in this the architects have been eminently successful, so much so that in this respect the house is a typical country residence.

The members arrived at The Glen in the early part of the day. Mr. John Bryce, the architect, and Mr. T. Fairbairn, hon. secretary, were of the party. After a glance at the rural entrance lodge and the fine approach, a move was made for the house. Mr. George Herdman, estate factor, received the visitors, and the housekeeper, Miss Bruce, led the way over the mansion. The noble entrance hall panelled in oak and with a billiard-table, first attracted attention, and then a move was made to the drawing-room in the southern wing. The windows of this charming room command the Quair valley, looking its very best in the spring sunshine. A most elaborately decorated ceiling withdraws the eyes for a few moments from the pictures, which are the chief attraction. Sir Charles Tennant is well-known as a generous art patron, and in The Glen is stored a splendid collection of works in oil and water-colours. A landscape by Turner—*Forthill*—has a good position in the apartment and the Scottish Academician Ewbank's *South Shields Harbour* is nicely hung. There are fine examples of Creswick, Clarkson Stanfield, Roberts, Boughton, Topham and Lawrence. A boudoir opens off the drawing-room, and while the latter was dedicated for the most part to the English Academicians this bright little room has the walls covered with some of the best efforts of two of our Scottish artists. There are, for instance, from the brush of

W. E. Lockhart, *Burns's Funeral, The Auld Brig of Ayr*, and two views of Dumfries. More numerous even are the examples of the late Sam Bough, including such fine works as *Lincluden Abbey, Field of Bannockburn* and *Ellisland*. Clark Stanton and Barret are also represented. A visit to the library, with its oaken bookcases heavily laden, and an inspection of portraits of the Tennant family there hung, together with the truthful presentments of the Ettrick Shepherd, the author of the "Seasons" and the Laird of Abbotsford, was next followed by a survey of the dining-room. A splendid view is had from the windows of this large-sized room. The Fethan valley stretches before the eye, with Minch Moor in the distance, where the road winds to Innerleithen, and where the country residence is of Mr. Thorburn, M.P. for the county. As a foreground there is The Glen shrubbery, with the well-kept tennis-lawn close to the house, and the little rivulet of the Kilburn provided with sundry miniature cascades. This stream is better known as Lucy's Burn, associated with Laidlaw's touching ballad of "Lucy's Flitting," in which the old mansion-house is commemorated. Pictures again command notice, and on the walls of the dining-room are examples by Watts, Erskine, Nicol, Alexander Fraser and a pretty river scene from the brush of G. Paul Chalmers. Retracing their steps to the hall, the party next ascended by a fine oak staircase to the floor above. A framed certificate on the corridor wall shows that at the Royal Jubilee Manchester Exhibition Sir Charles Tennant had a splendid collection of his pictures out on loan. A charming little room—Miss Margot Tennant's boudoir—received a due meed of approbation. Sitting at the window a pleasant view is had of the terraced grounds, with the upper part of the Quair valley, and to the west the bracken-covered Birkhill. A bright wall-paper and a carpet of deep blue, flecked with white, make the room cheerful, and a little cottage piano has the post of honour. Books are everywhere. Scott's novels, Edgeworth and Sterne are authors easily noticed; and the much-talked-of novel "Robert Elsmere" is on the adjoining shelf to a complete edition of Fenimore Cooper. Several paintings and engravings are on the walls, including Sam Bough's *Aberdeen*. Near the boudoir are two airy rooms, formerly occupied as day and night nurseries, and now known as Miss Tennant's rooms. The latter—the bedroom—is a quaintly-furnished apartment provided with many curios, antique nick-nacks and old china, and in every corner and nook well-laden bookshelves, on which are a number of religious works. Old-time prints are on the walls—hunting scenes mostly; foxes' heads and brushes are artistically arranged, and there is an array of riding whips depending from hooks. Recesses are formed by turrets at two angles of the room, and one of the little circular enclosures with bare stone walls and diminutive stained-glass windows is fitted up with a prie dieu.

After a careful inspection had been given to the house, and the architectural features closely scanned, an ascent was made to the flagstaff tower, and a grand sweep of the landscape enjoyed. This concluded the indoors part of the proceedings, and a tour was next made through the magnificent domains of the gardener. On the way the extensive stables drew attention, and a small snuggerly or smoking-room of Mr. Edward Tennant's, which is so filled with preserved trophies of the chase that it resembles a museum, was visited. A walk through the hothouses, under the guidance of Mr. James M'Intyre, head gardener, was a pleasant experience. Mr. M'Intyre is well known as a successful exhibitor, and at the Edinburgh show recently he had a considerable share of the honours. Grapes, pines and strawberries were seen in various stages, and in the orchid house, for which The Glen is noted, there was a splendid show. Partly driving and partly walking, the Edinburgh visitors then had a glimpse of a portion of the demesne. Higher up the Quair valley an artificial loch of some ten or twelve acres extent has been constructed, with islands, and with a picturesque boathouse. A footpath leads from here over the hills to the Yarrow valley; and St. Mary's Loch, it may be mentioned, is by a hill path only two hours' walk from The Glen. Within easy reach of the mansion-house are the attractive residences of the factor, head-gardener and head-keeper, and there is a neat schoolhouse for the estate children, with dwelling-house attached for the schoolmistress. A well-appointed dairy is in the vicinity of the gardens, and a covered-in tennis-court has been erected nearer the lodge gate. There is a post-office established for the estate, and at present a telephone wire is being brought out from Innerleithen.

During the course of the visit lunch was served in a summer-house, and one of the members of the party, Mr. Balfour Paul, Lyon King of Arms, Edinburgh, proposed a vote of thanks to Sir Charles Tennant for having given them permission to go over The Glen, and to Mr. Bryce for the explanations he had furnished in regard to the building. Mr. Herdman briefly replied, and said he was quite certain that Sir Charles would, if at home, have been glad to have met them, and would be pleased to learn that they had had a pleasant visit.

THE GLASGOW RAID.

THE printsellers in Glasgow who were compelled by the chief constable to remove some photographic reproductions of modern pictures from their windows, having informed the artists of the circumstance, received the following replies:—

2 Holland Park Road, Kensington, W.:

April 17, 1894.

Dear Sirs,—I learn with surprise and regret, from your letter of the 12th inst., that Glasgow—alone, I think, among the large cities of Great Britain—still lags in the stage in which works, inspired simply by the desire to express the dignity and beauty of the noblest work of creation, the human form, awaken only suggestions of obscenity. This, however, cannot be dealt with from without, certainly not by action on the part of the artists who produce these works. Time alone and the increasing influence of the more enlightened among your citizens, who are no doubt many, can be looked to to bring about a more wholesome and, let me add, cleaner attitude of mind.—Yours faithfully,

FRED. LEIGHTON.

The Avenue, 67 Fulham Road, London, S.W.:

April 18, 1894.

Dear Sirs,—It seems rather strange that I should be asked whether I consider a picture which I have painted objectionable on the score of decency. If there were anything indecent in it I should not have painted it. As a matter of fact, there is nothing in the picture which is indecent, and it is simply as insulting as it is idiotic to suggest such a thing.—Yours truly,

E. J. POYNTER.

74 Fellowes Road, South Hampstead,

London, N.W. : April 14, 1894.

Dear Sirs,—I am astonished that a request to remove the prints you mention should have been made in Glasgow—a city considered here as the art centre of Scotland.

I quite agree the matter should be taken up, and have every confidence that you will have the support of every art dealer and artist in the kingdom.

It is impossible that such a narrow and ignorant command should be recognised as final.—Yours faithfully,

ARTHUR HACKER.

2 St. John's Wood Studio,
Marlborough Road Station, N.W.:

April 20, 1894.

Gentlemen,—I confess that the action of your chief-constable in suppressing the exhibition of the works you name has not changed my views on the nude in art.

The figure of Justice is generally clothed and always blindfolded, the sword (I blush to think of it) naked, and the scales empty.

From my earliest youth I wondered why she was sightless. The problem has been solved in Glasgow. I take it she may not see the difference (a not very subtle one) between the naked prostitute and the pure unconscious type of female beauty. It is almost time Justice began to see something.—I am, &c.,

SOLOMON J. SOLOMON.

Messrs. Connell & Sons have also received the following letter from Mr. Arthur Lucas, the publisher:—

31 New Bond Street, W., London:

April 19, 1894.

Gentlemen,—As you invite my opinion upon the question of the public exhibition of reproductions of paintings of the nude and semi-nude, I must confess that, coming as I do of a family of painters, and having been engaged throughout manhood in art publications, it is difficult for me to understand the attitude of the chief-constable of Glasgow in requesting you to remove from your window such works as *The Bath of Psyche, Diana and Endymion, A Visit to Æsculapius, Orpheus, The Judgment of Paris*, and *Syrinx*, all of them works of truest art and of the utmost purity. He must be a debased brute indeed to whom any one of these could suggest impurity. But there are nudes and nudes, and whilst I have nothing but admiration for works of the above order, there are many (almost invariably by foreign painters) in which the nude is introduced in such a way as to degrade art and to debase the spectator. I would have such painters publicly flogged by the common hangman, and the men who deal in their wares prosecuted as public nuisances.—I am, gentlemen, yours faithfully.

ARTHUR LUCAS.

Dr. J. Hopkinson, F.R.S., will deliver the second "James Forrest" lecture at the Institution of Civil Engineers on Thursday next. The subject will be "The Relation of Mathematics to Engineering."

DOORWAY IN THE CHURCH OF THE ROSARY, TERLIZZI.

THE doorway of the church in Terlizzi (Apulia) was, like the rest of the front of the building, covered with a thick coat of whitewash. The Italian Government ordered that the door should be revealed, and were rewarded by a remarkable example of sculpture. The ornament, it will be observed, runs around the sides and upper part of the door, and consequently the elements which compose it are turned in different directions

according to position. The curves of the branches are stiff, but the sculptor may have tried to imitate nature. The upper relief in the arch is probably the strangest representation of the Last Supper that has been carved. In order to display the viands, the table becomes a sort of arch, and the Apostles appear as busts placed on it. Apparently they are Normans. The frieze represents the Annunciation, Nativity and Crucifixion, and the whole sculpture may be considered to be the work of some primitive amateur, and probably he was a Norman soldier.

DOORWAY IN THE CHURCH OF THE ROSARY, TERLIZZI.
By Anselmo da Trani.

THE EXPLORATION OF SILCHESTER.

FOR something like fourteen centuries, says the *Daily News*, the site of the once-flourishing Roman city of Calleva, in North Hampshire, better known to latter times as Silchester, had remained practically undisturbed by those potent weapons of modern archaeological research, the spade and the pick, when the late rector of Strathfieldsaye began, in an irregular way, to dig, with results interesting in themselves and rich in promise of future discoveries. Since then, however, a Silchester Exploration Fund has been formed, and the Society of Antiquaries have taken up the task in a systematic fashion, mapping out the whole area, extending to more than 100 acres, within the ruined and ivy-clad walls and the surrounding fosse, into square divisions, called by them "insulae," and devoting themselves to the examination of these, one by one, in a way which promises to place us eventually in possession of all that the remains of this once-important city can teach regarding the domestic life of the Romans in these islands. Meanwhile, with a view to sustain interest in these labours, they have instituted in the Society's rooms at Burlington House an annual exhibition, of which the fourth of the series was opened to the public on April 24.

Fortunately for the explorers, the church and a farmhouse are now the only buildings to obstruct their operations within the area, and, with the exception of some acres of pasture, the whole is arable land. The fourth season's excavations were begun early in May, and carried on till October 19. It is of interest to note that out of the Society's modest income for the past year, 374*l.* went in wages to the diggers, numbering some forty men all told, who are mostly labourers from the neighbourhood. They may be seen wheeling their loaded barrows in the elaborate and beautiful coloured model of the recent operations prepared by Mr. G. E. Fox and his brother enthusiast, Mr. St. John Hope, which, next to the great plan hanging on the walls, will attract the attention of visitors. A curious feature about the site is that it forms an irregular polygon of sixteen sides—an unusual form for a Roman city; but Calleva is believed to have been the site of *Caer Segont*, the more ancient capital of the *Segontiaci*, who once inhabited this part of England, and it may be that the Roman occupiers found its present configuration ready to their hands. The drought, by hardening the land, proved last summer a serious hindrance, but nearly nine acres were nevertheless explored, and much brought under observation. One condition, at least, is fortunate. Roman London is found at 16 to 20 feet below the present surface of the City, but the ground floors of the Roman buildings in Silchester are, as a rule, at a depth of little more than a foot or a foot and a half. It is not supposed that this once-flourishing centre of Roman life suffered anything like sudden destruction. In digging at War Bank, near Keston, Kent—supposed to be the site of a suburb of the great Roman city of *Novio Magus*—and elsewhere, unmistakable evidences of destruction by fire—the probable work of Saxon or Scandinavian invaders—have been found; but the tokens revealed so far at Silchester suggest that the ancient city simply decayed after the decline of the Roman power—shrank by degrees somewhat as *Winchelsea* has shrunk in later times, then became a village, and ultimately faded out—for the modern village of Silchester is some half-mile distant. The peculiar and most interesting feature of last year's operations was the light that they tend to throw upon the form and arrangement of the two distinct types of Roman dwellings—one known as the "courtyard," the other as the "corridor" type. In the division marked on the great wall-map as *Insula VIII.*, an unusually perfect house of the "courtyard" type was uncovered and a model of it made before it was covered in again; for it is to be observed that the covering-in process, though laborious and costly, is deemed to be the best for preservation. The "courtyard" style, as will be expected, was the more luxurious and important. It generally consisted of three sides, around which the various buildings were arranged. Adjoining to this unusually perfect model of a "courtyard" house is another house of the corridor kind. This is simply a long house consisting of a row of chambers, with a corridor on either side. These buildings flank the main street of the city, which passes straight from north to south. All the streets, indeed, are laid out in this Roman fashion, direct from point to point. This reminds us that the great drought of last season was not entirely a misfortune; for the consequent withering of the clover and vegetation along its course led to the discovery of a hitherto unnoted street, running from the north wall to the south wall of the city, and forming the eastern boundary of *Insula VIII.* Even learned antiquarians have been apt to forget that differences of climate necessarily led to essential changes in the form and arrangements of Roman dwellings. The houses in Britain and in northern Gaul were, indeed, entirely different in their arrangements from those of *Pompeii* and the countries skirting the Mediterranean. Our Roman masters shivered in our east winds and hated our damp atmosphere. Hence their dwellings here were more closed in, and had, as a rule, no

great peristyles or open atria. In *Pompeii* hardly an instance has been found of means for warming houses. In Silchester, on the contrary, there was scarcely a room without a "hypocaust" under its floor, with an adjoining furnace in which charcoal was burnt, the heat thus generated and stored being thence circulated through the walls by means of fireproof flues formed of brick and tile.

Within the area of the present explorations is the Forum and Basilica, with the adjoining baths; also a circular temple with its adjoining small enclosure, supposed to have been a temporary "pen" for victims. The amphitheatre, which measures fifty yards by forty, stands at some 150 yards outside the north-east gate. Though now overgrown with trees, its double entrances and five ascending ranges of seats are still readily distinguished. The antiquities found last year, though not so numerous as those of the previous season—a circumstance attributed to the unusual hardness of the soil—include many objects in bronze, iron, bone, glass, and even wood. Several important architectural remains were also discovered, among which is an absolutely unique object found in a pit—being the greater part of a "stele," or turned pillar, bearing a legible monumental inscription in the ancient "ogham" characters. On this find Professor Rhys will doubtless have something to say. Hitherto no ogham inscription has been discovered east of Devonshire or the river Severn. The occurrence of this unexpected and undoubted example so far east as the Duke of Wellington's estate at Strathfieldsaye has occasioned a flutter in the western wing of Burlington House, which only perhaps an earnest member of the Society of Antiquaries can fully appreciate. The general collection of Silchester objects which will be on view next week is very considerable. They include coins—from those of *Vespasian* to those of *Honorius*, which recalls the fact that according to *Nennius* it was in the time of *Honorius*—that is, early in the fifth century—that the so-called "Usurper" *Constantine* was crowned in Calleva, where, according to an old local tradition, either he or his son *Constans* sowed three grains of wheat within the walls which had the mysterious virtue of protecting the inhabitants against poverty. Gold coins of the Celtic type have ere now been discovered at Silchester; also many inscriptions, among which is a fragment of an altar, "To *Hercules* of the *Segontiaci*." For the rest, the finds have mostly consisted of seals, rings, glass and personal ornaments, mosaic flooring, and so forth. A noteworthy object shown on Saturday was a curious squat earthenware bottle, belonging to the latest stratum of relics. It is in shape like two very large circular buns, placed flat-side to flat-side, and having in the centre of one of the convex sides a very short neck. A tiny perforation near by fulfils the obvious purpose of the spigot hole in a barrel. Altogether about thirty-six out of the hundred acres have now been excavated and planned, from which it will be seen that the Society have yet some years of hard, and we trust fruitful, work before them.

THE FREE CLASSIC REVIVAL OF 1870-80.*

(Concluded from last week)

SUCH were the beginnings of modern Queen Anne. From small school edifices it developed into an harmonious and well-defined type of domestic building—very different in its letter from the stiff and starched appearance of its prototypes, being marked by breadth and freedom of treatment and in many cases by great richness of detail. The movement for an improved architecture was not confined to England; the architects of the United States soon caught their enthusiasm, and the Centennial Exhibition of 1876 served to intensify the feeling of patriotism. If Queen Anne architecture were dear to Englishmen, it was reasoned, it should be doubly so to us. In England the history of architecture could be traced back for centuries. In the United States the case was different. The early colonists landed in America while Jacobean architecture was at its best, but they could give little thought to style or details; protection from the elements and savage foes were the first requirements. Later, when they could give more attention to architecture as an art, Queen Anne ruled the popular taste and our colonial mansions were built and decorated under the influences that surrounded the thought and literature of the time.

Queen Anne or Early Georgian is therefore our starting-point in architectural history. It has been well to revive a taste for its quaint and home-like character, not merely for its own sake, but as a stepping-stone to something better and more enduring for the future.

Let us now briefly glance at the various constructive features embraced in what has thus been outlined as Queen Anne architecture.

* An address by Mr. George C. Mason, jun., delivered at the Architectural School of the University of Pennsylvania, and published in *Architecture and Building*.

Construction.—In the Renaissance of Palladian detail and Dutch brickwork welded together as the principal factors of Free Classic we can distinctly trace the influence of three systems of construction.

1. In dignity, as in age, stands the cottage or Old English style, claiming descent from the heavy Tudor mansions of rough stone, unhewn timber and white concrete filling, usually termed "magpie work," from the startling contrast between their white panels and tarred timbers. Of these old mansions numerous examples still remain; they were, for the most part, erected during the fifteenth and sixteenth centuries, but in some instances a much earlier date may be assigned them. Their construction is of the most substantial character and consists in great part of oak framework of large scantling, tenoned and pinned together, the spaces between the timbers being filled flush both sides with a composition of well-beaten clay, straw and chalk, which has become almost as hard as stone. Imbedded in the composition are stout oak laths held in position by cross sticks, to which they are bound by hazel withes, no nails being used in any part of the work.

2. Queen Anne proper, founded on the houses of Holland and the Netherlands; a thoroughly appropriate system of construction for a country where brick is the vernacular building material, and one which, perhaps, of all others, is the most easily adapted to the requirements of city streets, with but little width for the façades and with lofty gables to give additional storeys to meet the various needs of traffic and domestic life.

3. The style without a name, but which in the early years of the Renaissance gathered to itself a heterogeneous mass of details, both insular and continental, combined with a picturesque grouping of parts to form a well-defined and pleasing whole. This later phase may well be called "Free," but as it appears to be simply a stepping-stone to something better and is still in process of amalgamation and expansion, I propose to call it the Victorian Transition.

The originators of modern Queen Anne were all men trained in the Gothic school and their watchword was "true construction." This term seems to be the most elastic and enduring of all the rules of architecture. It is, however, applied mostly to the works of a revival period, and is frequently used in advocacy of new methods and in condemnation of the old.

The architects of the Victorian Gothic school had had it impressed upon their minds by the teachings of Pugin, Eastlake and others, that true construction did not exist after the Middle Ages; the period of massive timber framing, heavy tables, mantel trees and settles, put together with wooden pins and disdaining all curves and wavy lines. For a time these professors of artistic truth were implicitly believed, and architects came to look upon stucco, plastering, glue, veneers, broken pediments and applied ornamentation as monstrous emanations from diseased brains, bewildered and carried off their balance by the great upheaval of the Renaissance. The rapidity with which a change in sentiment was achieved is one of the most remarkable instances in architectural history. The worshippers of "savagery" and all the elegant diction of the "Seven Lamps," the plaster ornament breakers of 1860, became ten years later the loyal subjects of Queen Anne, accepting without question the tenets of Stuart and Revett, the Adam Brothers and even of Nash and Wyatt, who carried the extravagance of applied ornament to its utmost limit.

In studying the constructive features of the Queen Anne Renaissance we find many examples of richly ornamented façades, combined with an affected picturesqueness and quaintness unthought of two hundred years ago. How are we to account for this change in favour of greater richness and profusion of detail in a professed revival of the pure and simple forms of the past, and for the well-established fact that modern Queen Anne brickwork owes much of its effectiveness to the teachings of an earlier school—that of the Tudors?

Art brickwork as we find it used in English architecture is not simply an outgrowth of the Dutch school introduced on the accession of William of Orange. For centuries it had been employed with success, particularly in Norfolk and other "brick districts." Under the Tudor sovereigns moulded and carved brickwork attained a high standard. The buildings erected under their rule were frequently enriched with delicately-carved and wrought string moulds, gable ends, chimneys, cornices, sharp in outline, crisp and spirited in detail. Even under the Stuarts, Inigo Jones and his great successor, Wren, executed some noble works in this material. Unfortunately for art, Parliament in 1625 established the rectangular dimensions of bricks, which thenceforth were moulded in one dreary pattern, a block of burnt clay 9 by 4 by 2½ inches. In 1784 Parliament again interfered and levied heavy taxes upon all bricks modelled, whether such bricks were spoiled in the burning or not. This tax was in its action almost prohibitory of any attempt at establishing a high grade of workmanship. In the long interval between 1625 and the repeal of the tax in 1850 workmen in clay forgot their cunning and all desire for improvement had come to a standstill. The Victorian Gothicists made strenuous efforts to reform so dis-

creditable a state of things, and, after struggling for years against the conservatism of brick masters and the ignorance of labour, attained their ends. Thus, when the School Board Act of 1870 was passed, it found them ready with trained mechanics at their command. The opportunity was not lost and the new Queen Anne was born. In 1850 the revival and expansion of that style would have been impossible. In 1870 the building world was ripe for the change. The architects themselves, after receiving their early education under the leaders of the stucco and plaster school of the Georges, had become purified and refined by the art teachings of the Gothicists. The result was a spontaneous movement to develop a new system of construction with lintelled openings and square fenestration—Queen Anne modified and elevated by Mediaeval traditions. A transitional manner, but a sensible one; a sudden fashion; if you will, a craze; but it is a monument which will be looked back upon with satisfaction, as a bold and successful step toward the solution of the great problem of domestic architecture, how to make every man's home his proper dwelling—how to combine Sir Henry Wotton's three conditions of the art of well building, "commodity, firmness and delight."

Esthetic Qualities.—Having thus followed Queen Anne architecture through the various phases of its development, it but remains to refer to its claims to artistic excellence, and answer, if possible, the question so frequently heard ten years ago, "Is Queen Anne high art?"

Two thousand years ago Vitruvius laid down the following rules as the basis of good architecture:—First, order, method and regularity. Second, fitness of arrangement, general disposition and contrivances adapted to locality and other circumstances. Third, uniformity. Fourth, proportion, being the relation of parts or quantities, by which harmony and grace are obtained. Fifth, character, which dictates the special aspect of the work according to its purpose. Sixth, analogy, consisting in those resemblances and ideal significances which assimilate the works of man to those of nature. Seventh, economy, not merely the vulgar economy of the purse, but that which combines utility with beauty, admitting nothing superfluous and allowing nothing to be overlooked.

Sir Henry Wotton tells us in the quaint language of his day that "in architecture, as in all other operative arts, the end is to build well." Other writers have alluded to architecture as the "politeness of building" and as "the art of building with expression." Nothing, however, so happily expresses the fundamental law which should govern the preparation of an architectural design as these words of Roscoe:—"Utility and beauty are bound together in an indissoluble chain, and what the great Author of nature has joined together, let no man put asunder."

Will the Free Classic of the Queen Anne reformers bear the test of a critical comparison with the "Seven Lamps" of Vitruvius, or the elegant diction of Roscoe? Are such designs true exponents of "high art," and will they meet the requirements of modern life and its complex and artificial conditions?

We have seen that the United States received their colonial methods of building direct from England, but here the connection ceases, except in sentiment. If we compare a number of designs for English and American country houses, with their accompanying plans, we will, I think, discover that in reviving a taste for Queen Anne composition the architects of the two countries have adopted different ideals as to the inception and development of their eclectic systems. The Englishman, naturally conservative, clings rigidly to his first ideas of domestic planning, and, although varied and often enriched in detail, the exteriors of his Queen Anne houses are in most instances simply reflections of earlier works designed for the School Board of London. The planning of their houses is irregular in the extreme, symmetry and balance of parts is ignored, and the communications between the various apartments complicated and often tortuous. Their long and narrow corridors, and the infrequent use of the furnace or steam coil, as a means for procuring an equable diffusion of heat, supplemented by open fireplaces, necessitates the screening of doors by placing them in out-of-the-way angles to prevent draughts. The humid climate of England renders the verandah objectionable, and the windows, rarely fitted for blinds, are grouped together and divided by light and graceful mullions—a relic of Tudor practice.

The American architect started to perfect his revival with less precedent and conservatism to contend with. He could therefore adopt any system he pleased, or, by combining several styles, compose a thoroughly eclectic design. Truth compels the confession that he took full advantage of his opportunities, and his Free Classic became free indeed.

No style of domestic architecture can be good or partake of high art qualities that cannot be claimed as a true exponent of the family and social life of the period to which it owes its birth and development. A whimsical fashion in dress, in equipages, or in the etiquette of society can be tolerated without injury to national advancement. Such fashions are transitory, springing suddenly into notice and as rapidly passing

into disuse. With architecture it is different. Her follies are wrought in durable form. We see an ultra Queen Anne house erected during the height of the revival period, and its quaintness and odd conceits attract our notice and perhaps enlist our passing commendation. If we live in it we put up with its soon apparent incongruities, and for a time all goes well. But, when we tire of four by four-inch fenestration, glazed with rough cathedral glass; with the lines of the quaint tower, several inches off the vertical, and bulged in the centre of its height, to give the effect of age; with the rough and, at first sight, massive walls, of lath and plaster, glittering with broken glass; with ceilings so low that we are unable to fit our rooms with chandeliers, and thus diffuse a proper light over apartments rendered gloomy with artificially darkened walls and panelling, what are we to do? If the house is well built, it should be in better heart and condition one hundred years hence than the colonial mansions erected prior to 1760 are to-day. These colonial mansions, built and furnished for the wealthy merchants of the seaboard towns, may well command our admiration and careful study. As a rule, they are entirely unfit for the domestic life of to-day, and their construction is faulty and badly designed when viewed in the light of the best modern practice. They should, however, be studied, because they are true exponents of art building, in that they show in every line and moulding good common sense—the use of materials according to the best ability and knowledge possessed by the artisans who erected them, and a sturdy manhood which wrought by main strength artistic works out of the crude materials and slender mechanical appliances of the colonists. A study of these old mansions seems to lay before us something of the mental strength of the men who erected them—men who were fully up to and even ahead of their time, and who aimed to do their best, and what they did was good. Such being the case, are we to suppose that had the colonial architects and builders continued in practice down to our own times, they would have gone on in the old way, or rather behind their own best period of construction? To revive, under the title of “Queen Anne,” and to meet a popular fad in the last quarter of the nineteenth century, the hewing out of huge beams with an axe, leaving them as large as possible to reduce manual labour to a minimum? No; they were too advanced in sentiment for such weakness, and would, no doubt, have developed by steady growth a sensible and correct national style of domestic building, founded upon colonial precedents; but taking into consideration all the advances in science and art, and above all in machinery, which, although frequently decried by “high art” amateurs, has done more to improve the art and science of American building than all else besides.

The advanced Queen Anne designer of the early revival period took a different stand and used different arguments. He told us in all seriousness and with much enthusiasm that the domestic building of the colonists was far in advance of modern work in homelike comfort as well as in picturesque aspect. He pointed to the huge beams and hanging knees which support their floor, the rudely chamfered edges doubled into shape with an axe, as evidences of the care and skilful manipulation of the workman. He called upon us to admire the hand-made sashes, with muntins an inch and a half in width, glazed with rough and greenish glass; the mouldings, all hand-made, showing all the wavy lines and irregular sections inseparable from hand-work, and then triumphantly asked, “Can your boasted machinery turn out such work as that?” I answer, emphatically, No, it cannot; and for this we should be thankful. Would such men as the colonial builders, whose best work is their monument, have spent their time in hewing out beams of oak 10 or 12 inches square by main strength and patience, if they had possessed the circular saw driven by steam power? The weight of these huge beams, of badly-proportioned section, forced to support a surplus of width with comparatively slight depth, wrought serious injury to the building of which they formed a part, settling floors, hollowing roofs and ridge lines and doing far more than time in rendering these old mansions picturesque suggestions for a revival of “high art.”

Thus we have followed the revival of 1870, its gradual development and culmination about 1880; and now, twelve years later, our architects begin to feel that the sound common sense that underlies the mental nature of our people is encouraging the growth of true art culture. This feeling reacts upon our architects, and with better educational facilities than any of the men of middle age have ever possessed, we are moving out on truer and more deeply laid plans for the improvement and development of our national architecture. So far we have had in this country no fixed standards by which the educated architect could be tried and his professional position established. Unlike the practice of law and medicine, the field has been free to all, and previous training not required. The establishment of architectural schools at the Massachusetts Institute of Technology, at Columbia College, at Cornell University, at Champagne, Illinois, and within the last four years at our own University, with well-trained and enthusiastic professors at the head of each, with carefully selected assist-

ants, is already doing much toward an improvement in students and in raising the standard of our architects in the eyes of society. This student system must in time create a body of men well trained, enthusiastic, and bound together with an *esprit de corps* hitherto unknown among the great body of practising architects. The dictum passed by such a body upon questions relating to their art will be received with respect by the laymen who employ them, and our American architecture will thus receive an impetus and acquire a nervous strength in construction and composition which at present we find exemplified only in the works of a few highly-trained—generally self-trained—practitioners.

The Queen Anne revival, viewed apart from the incongruities that became engrafted upon it, has proved a movement of great interest to the profession. Although adopting a worn-out and debased art as the foundation on which to erect their eclectic system, the revival has given to us in the works of its best masters much that is beautiful and honest in theory, and added to real domestic comfort. To Americans, Queen Anne or Early Georgian is the starting-point in architectural history. Let us then accept the position, and aim to emulate the old masters in their endeavours to do the best with the small means at their command. Let us build strongly, honestly and conveniently, eclectically, if we will, and our nineteenth-century architecture, developed from and founded upon Queen Anne, will realise the ideal of Skelton, who tells of the early masters who, centuries before the advent of Queen Anne or Free Classic architecture, were—

Building royally
Their mansions curiously,
With turrets and with toures,
With halls and with boures
Stretching to the starres;
With glass windows and barres;
Hanging about the walls
Clothes of golde and palles,
Arras of rich arraye,
Freshe as flowres in Maye.

GLASGOW BUILDING TRADES' EXCHANGE.

A GENERAL meeting of the members of the recently formed Building Trades' Exchange for the city and district of Glasgow has been held, for the purpose of considering the report of the committee appointed to draw up a scheme for the organisation of the Exchange. Mr. Andrew Gray, who presided, said it was very gratifying that the matter of the Exchange had been gone into so actively, and he was glad to see present representatives from the architects, measurers and builders in the city. They wished to have the hearty co-operation of all connected with the building trade, as the Exchange was intended to assist all connected with the trade. He had not the slightest hesitation in saying that he believed that before long they would have one of the best Building Exchanges in the world, not even excepting any of the flourishing exchanges in America. The report regarding the organisation of the Exchange was then submitted. The Association is to have a capital of 10,000*l.*, divided into 1,000 shares of 10*l.* each, and the membership is to be of a corporate and non-corporate character. There is to be an executive council of twenty-one members. The report was adopted, and Mr. W. M. Cunningham was elected secretary, and Sir William Arrol president. Various committees, including those on arbitration and education, have to be appointed.

THE BATH PUMP-ROOM ANNEXE.

AT last week's meeting of the baths committee of the Town Council the proposal for the erection of an annexe to the Pump-room was considered. Mr. J. M. Brydon, the successful competitor, produced two plans which he had prepared. These were lettered respectively “A” and “B.” “A” provided for a promenade-room running in the same direction as the existing Pump-room, that is, from Stall Street towards the abbey, with additional offices, the whole to cost 19,000*l.* The “B” plan provides a promenade-room running from the direction of Cheap Street towards York Street, the dimensions being 60 feet by 40 feet. On the right hand of the entrance from the churchyard ladies and attendants' rooms and a parlour would be arranged, while on the left there would be cloak-rooms and a smoking-room for gentlemen. Down each side a kind of corridor would run, ending in a terrace at the southern end overlooking the present Roman baths, which would be covered by a single-span roof, the elevation of the whole being the same as the existing Queen's Bath. Care would be taken not to interfere with any of the Roman remains, while the building itself would be 37 feet from the abbey at the nearest point. For the purpose of this plan it would be necessary to pull down

Mr. Moody Davis's premises, but the further half of the block would not be needed. The corridors would have low roofs, but the promenade-roof would form a dome. The cost of "B" plan would be just under 20,000*l*.

It was moved that the plans should be left at the Guildhall for further inspection by the members of the committee, and that Mr. Brydon draw up a description which might be printed and circulated amongst the members.

An amendment was proposed by the Mayor, and seconded by the ex-Mayor, that the committee recommend the "B" plans to the Council for acceptance.

After discussion the amendment was withdrawn and the original motion carried.

SIR SIMON PRESTON'S HOUSE, EDINBURGH.

A TABLET with the following inscription has been placed on the wall on the west side of the entrance to the Royal Exchange, Edinburgh:—"On this site stood the mansion of Sir Simon Preston of Craigmillar, provost of the city of Edinburgh, 1566-67, in which mansion Mary Queen of Scotland, after her surrender to the Confederate Lords at Carberry Hill, spent her last night in Edinburgh, June 15, 1567. On the following evening she was conveyed to Holyrood, and thereafter to Lochleven Castle as a State prisoner." This tablet, marking the site of so interesting a tenement associated with Queen Mary's history, has been erected as the outcome of a motion made in the Town Council last year by Dean of Guild Miller, who has since greatly interested himself in the matter. In his researches the Dean has had the benefit of the antiquarian knowledge of Mr. Peter Miller, one of the ex-bailies of the city, who has drawn up a memorandum on the subject, founded largely on a scrutiny of the sasines or title-deeds of the property in this locality. In this document Mr. Miller says:—"That the house occupied by Sir Simon Preston, provost of the city in 1566-67, when Queen Mary was lodged in his house, was on the north side of the High Street, forment the Cross, is proved by the letter, written the day after the occurrence took place, of J. Beaton, brother of the Archbishop of Glasgow, wherein, among other incidents related concerning Queen Mary at that time, he says:—'The Lords brocht her Majestie to town, quhair they arryvit at 10 hours. They logit her Majestie in the Provost's lodging, forment the Cross, upon the north side of the gait.' (See Laing's 'History of Scotland,' third edition, 1819, appendix page 109.) Sir Simon Preston was provost of the city of Edinburgh at that time. Sir Simon Preston's family owned the mansion at the Cross from 1493 till after Queen Mary's time. The house was some time afterwards sold to Alexander Mauchan, advocate, and it was sold subsequently by his heirs to Walter Stewart, writer, of Ballachtoul. The exact site of the house of Sir Simon Preston is ascertained from Edgar's map of 1753, before the Royal Exchange was built, as it shows all the closes in that locality. The Ordnance Survey of the locality in 1859, which shows the lower ends of Stewart's and Pearson's Closes, also supplies us with evidence by which it can be determined, on the line of the High Street, where the closes named open on that street. From the sasines referred to, it appears that there were two tenements between Alexander King's Close and the west side of Preston's mansion, and that mansion was bounded on the east by Preston's Close, afterwards named Stewart's Close, and that close formed the west boundary of Alexander Pearson's house. From these it is shown that Preston's mansion stood on the west of Stewart's Close. The survey plans show that Stewart's Close opened on the High Street, where the entrance to the Exchange now is, so that Preston's house stood partly on the entrance to the Exchange and partly to the west of it."

Fireproof Construction.

SIR,—Some short time ago there appeared in one of the building papers a letter from a northern architect to the effect that "Some little time previously he had constructed a mill or factory on the latest fireproof principles. Some time afterwards he received an intimation that the mill was on fire, and in a very short space of time it was burned to the ground, although it was supposed to be fireproof."

It is a well-known fact that in buildings of this description, although the floors are to all intents and purposes fireproof, as soon as the columns and main girders which carry the same get red-hot, they bend or buckle under the weight they have to carry and let down the lot, roof as well, into the furnace which is burning beneath. I thought a good deal about this

matter at the time the letter appeared, but could not then see my way clear to answering the same; but now I am in a position to do so, and take this opportunity through the medium of your paper of announcing, for the benefit of this gentleman, as well as others whom it may concern, that I have obtained provisional protection for an invention by the use of which neither the columns, main girders, or floors can either bend or buckle, even when subjected to the most intense heat, thus making buildings fireproof beyond all doubt. I have many details and improvements which will be included in my complete specification, but in the meantime, in the interests of the public, I am willing to give architects and others (bona-fide) an opportunity of at least considering my invention.—Yours faithfully,

CIVIL ENGINEER.

32 Lydford Road, Maida Hill, W.

GENERAL.

Members of the Architectural Association are informed that through some misunderstanding the Westminster Town Hall is not available for the Architectural Association *soirée* on May 4, but that the Holborn Town Hall has been taken for the performance of the play for that date.

An Exhibition of works of past and present students of the City and Guilds of London School of Technical Art, established in Kennington Park Road in 1879, will be held in the hall of the Skinners' Company, Dowgate Hill, from May 1 to May 9. The exhibition will include works of sculpture, modelling, engraving, drawing, painting, design, house decoration, wood engraving, &c.

The Paisley Burns Statue Committee have requested the following sculptors to send in models for a statue of Robert Burns, to be erected in Paisley, at a cost of 1,300*l*.:—Messrs. John Tweed, F. W. Pomeroy, R. W. Colton, Wade, Whitehead, and Charles H. Allen, London; W. Birnie Rhind, W. G. Stevenson and George Webster, Edinburgh; Kellack Browne and William Sheriff, Glasgow.

A "Pig" of Roman Lead has been found on the moors near Matlock. It weighs about 170 lbs., has an inscription on its upper face, and in all respects agrees with the numerous other pigs of Roman lead found in various parts of Britain. The inscription, divested of ligatures, is P·RVBRI·ABASCANTI·METALLI·LVTVDARES, or "(the lead of) P. Rubrius Abascantus, of the Lutudarensian mine." Abascantus may be supposed to be the lessee of the mines, which were State property by Roman law.

The Surveyors' Institution will meet on Monday, April 30, when a paper will be read by Mr. Harold Griffin, entitled, "Weekly Property as an Investment." The annual dinner will take place at the Holborn Restaurant (Venetian Room), on Monday, May 28, at half-past six.

The Liverpool Architectural Society hold their annual general meeting on Monday, May 7, when the officers and council for the forty-seventh session will be elected, Mr. Henry Hartley being nominated for re-election as president.

An Anonymous Donor, who has been defraying the cost of the restoration of the battlements and clerestory of Kidderminster parish church, has decided to undertake the restoration of the tower, which will be recased with stone under the superintendence of Mr. J. A. Chatwin, architect, of Birmingham. This will entail a cost of several thousand pounds additional to the amount involved for the work already undertaken.

Mr. A. E. Cokayne, of Ilkeston, died suddenly on Tuesday night. He was the author of a comprehensive history of Haddon Hall, and was collaborator with the Duchess of Rutland in her literary work. Mr. Cokayne was an authority on heraldry.

Mr. S. S. Stanley gave an address on "Church Bells" at the annual meeting of the Warwickshire Archaeologists' Field Club just held.

The Royal Society of British Artists have elected the following members, viz. Messrs. Robert Christie, Reginald Machell, E. H. Read, Montague Smyth, Frank Spenlove Spenlove and Holland Tringham.

Mr. Herbert R. Lloyd read a paper on "A Group of Worcestershire Houses" at the Midland Arts Club, Birmingham, which was illustrated by lantern slides, shown by Mr. R. K. Dent. Many views of sixteenth and seventeenth-century half-timbered houses were shown.

The Nineteenth-Century Art Society have settled on Tuesday, May 1, for the reception of works of art intended for the Summer Exhibition (the thirty-second) at the Conduit Street Galleries.

The Members of the Carlisle Architectural, Engineering and Surveying Association have just held their third annual dinner and smoking concert at the Coffee House Hotel, Mr. Higginson, architect, president of the association, in the chair. There was a very large gathering, including several visitors.

The Architect.

THE WEEK.

THE appointment of Mr. E. J. POYNTER, R.A., to succeed Sir F. W. BURTON as Director of the National Gallery will give general satisfaction. It is preferable to confide so important a post to an artist rather than to an amateur or even an officer of engineers. Mr. POYNTER, by his *Israel in Egypt* (which is now an attraction in the Guildhall Gallery), *Atalanta's Race*, *Stoning of St. Stephen*, *A Visit to Esculapius*, *Meeting of Solomon and the Queen of Sheba* and other paintings, has demonstrated that he knows more about past life than is to be derived from historical primers. His lectures also are evidence that he has carefully studied the histories of all the schools of art. Mr. POYNTER, therefore, may be considered as having prepared himself for his present position by an effectual course. A German would say it is better to undergo training as an assistant, and afterwards to have charge of small galleries, before undertaking the responsibilities attached to the directorship of the most important collection in a State; but there are advantages in possessing the technical knowledge which is not obtainable in a bureau. Mr. POYNTER's association with South Kensington does not accredit him with the public, but as he always acted in an independent manner and endeavoured to minimise the evil effects of the departmental system, it would be an error to suppose that he became degenerated, like so many artists who had accepted official positions. Mr. POYNTER is the son of the late AMBROSE POYNTER, architect, who was associated with the organisation of the schools of design, and was a pioneer in the endeavours to overcome the indifference to art which prevailed among manufacturers and others.

THIS year's exhibition of the Royal Academy will not be memorable on account of one work, but it is likely to be attractive. There are nudities enough to tempt the Glasgow bailies to invade Burlington House and vindicate the cause of morality. In one instance the presentation of the undraped model is to be excused. By some odd attraction plain men have a wish to be represented by Mr. HERKOMER, and having painted so many portraits of them, it is natural he should for relief wish to paint a figure which was not concealed by black clothes, and did not suggest wealth. As Sir J. E. MILLAIS is absent, Mr. FILDES has obtained a chance to become the fashionable portraitist. His likeness of the Princess of WALES is so successful as alone to warrant a claim on that position. The immense example of decoration for a Boston library by Mr. SARGENT is the largest and most obtrusive example that has appeared in Burlington House. Another novelty is Mr. A. GOODWIN's celestial cathedral in blue, for which his water-colour drawing of Mont St. Michel in the Society's room was evidently one of the studies. It is as remarkable as any of JOHN MARTIN's attempts. The picture is only one of many colour experiments in the exhibition, and this year colour rather than form claims interest. In the sculpture-room Mr. GILBERT's design for the tomb of the Duke of CLARENCE will excite interest.

THE name of the Belgian painter, ERNEST SLINGINEYER, who has just died in Brussels in his seventy-first year, was almost unknown to the frequenters of modern exhibitions. Although he retained a large studio, he rarely worked in it of late years. M. SLINGINEYER married a baroness some years ago, and he gave up art for politics. As a representative he was always eager to serve art in Parliament, and from time to time he delivered eloquent speeches in its support. He was well qualified to become a minister of art, but we believe he never held office. M. SLINGINEYER was a pupil of WAPPERS, and was so precocious that he was able to produce his colossal picture of the "Vengeur" myth, which many consider to be his masterpiece, before he attained his twentieth year. His aspirations were towards monumental art, and the majority of his paintings could only be hung in public buildings. M. SLINGINEYER believed

in tragedy; hence battle scenes or catastrophes like the Destruction of Pompeii were his favourite subjects. When GALLAIT, DE KEYSER, and others of his countrymen, instead of epic themes, produced pictures of historical episodes, M. SLINGINEYER's style became old-fashioned; in reality, people found it was not pleasure to attempt to realise his subjects, while his rivals never attempted anything which the simplest could not enjoy. To many of the Belgians he seemed to be a successor of DAVID, whose theories and practice belonged to a sort of prehistoric age. His later contemporaries preferred anecdotes on canvas, while he painted history in the style of men who were accepted as great masters. Fortunately for him his activities were turned into a new direction. He retained a hankering after art, and it was not agreeable when he visited his studio to be surrounded by immense pictures which no Government would purchase; but the indifference did not make him bitter towards the younger school, and he spoke of contemporary painters with admiration, although they did not care to become his imitators.

STUDENTS of French Gothic and all who propose to undertake a journey in the French provinces will find it an advantage to possess the new number of the American *Architectural Record*. Among the contents is a chronological summary of the French cathedrals prepared by Mr. BARR FERREE and arranged in tabular form. About sixty years ago DE CAUMONT introduced summaries in his "Histoire," which was a *résumé* of a course of lectures delivered in Caen, and in 1843 the Abbé BOURASSÉ compiled a table for his book on the cathedrals; Mr. BARR FERREE's table is far more elaborate than the earlier attempts. He is not satisfied with giving particulars of the buildings which are at the present time accepted as cathedrals, but includes also churches which formerly were used as cathedrals, ruined cathedrals, temporary cathedrals, and churches which replaced former cathedrals. As a consequence, the number of buildings of which records are given is increased. The Abbé BOURASSÉ notices eighty-one buildings, while Mr. BARR FERREE has two hundred. The former employs six periods. Mr. FERREE describes the work executed in each century, an arrangement which required far more labour. The tables will be found most useful, not only to tourists, but as a chronological guide to one important class of buildings.

THE insertion of an architect's name in a prospectus may henceforth be taken as evidence that he was architect to the company in spite of other evidence to the contrary. That is the moral to be drawn from the judgment given by Mr. Justice WRIGHT in *CREWE & SPRAGUE v. Brixton Theatre Company, Limited*. The plaintiffs claimed that in November 1892 they were retained by the defendants to prepare the plans and procure tenders for the structure, which was to cost 13,000*l*. This work was done in due course, but in December the company dismissed the plaintiffs, as alleged, from their engagement, and engaged Mr. FRANK MATCHAM. The defence substantially was that the plaintiffs did the work for one BLACKMORE, and not at the request of or for the company, which was not incorporated at the time. The learned Judge, however, held that as the names of the plaintiffs were inserted in the prospectus as architects, and there was a paragraph stating what arrangements the company had made with them, in his opinion, although the plaintiffs could not establish the whole of their claim, yet they were entitled to something for their plans, and he suggested a settlement. The company had, it appears, made no use whatever of the plans, nor had they seen them. As it was found impossible to arrive at terms, his lordship gave judgment for the plaintiffs for fifty guineas with costs. The amount claimed was 1,000*l*.

THE award in the competition for the proposed meat market in Bradford Street and Cheapside, Birmingham, has been given by Mr. MURGATROYD, of Manchester, who was appointed as judge. The design by Messrs. ESSEX, NICOL & GOODMAN has been selected, Messrs. COSSINS & PEACOCK's design obtains second prize, and the third prize is awarded to Messrs. BATEMAN's design.

ARCHITECTURE AT THE ROYAL ACADEMY.

THE visitor to the Architectural Room is likely to be surprised at first by the exceptional largeness of several of the drawings. There are, however, others which are unusually small, and as a result the average number of drawings is attained. The names of many of the exhibitors are familiar, but this year some appear for the first time in the catalogue. London, as usual, holds possession of the larger part of the wall space, but Leicester, Chester, Bolton, Manchester, Liverpool, Brighton, Exeter, Gloucester, Harrogate, Kettering, Cardiff, Llandaff, Reading, Edinburgh, Glasgow, Douglas (Isle of Man), &c., have a share of it. The collection has, therefore, some claim to be considered as representative.

It may be inferred from the drawings that English Renaissance and Flemish continue to be esteemed as the most fitting styles for secular buildings, and that churches are generally Gothic of a somewhat elastic species. But there are signs of a slight agitation which may be interpreted as a preliminary to a nearer approach towards Italian. If clients were sufficiently courageous to pass the threshold of the room, it is not unlikely that many of them would be fascinated not only with the decoration in graffito of a house in Lisbon, by Mr. FORMILLI, but with the character of the house itself, and Scotsmen would conclude that, as the faceted masonry shown in the lower part was also to be seen in Crichton Castle, it deserved to be adopted for their London houses. There are also drawings of additions and alterations to buildings, like those which are seen in the "Vitruvius Britannicus," that men who contemplate building would consider as having a stateliness and repose which are not attainable in styles that allow the different parts to enter into competition with each other for prominence. Jardine Hall, Dumfries, and Wickham Hall, the former being entrusted to Mr. E. J. MAY, and the latter to Mr. W. MILLARD, are examples of old-fashioned houses which should not be considered as of obsolete types.

Domestic work is in the ascendant this year. The demand for picturesque country houses is suggested by the number which appear on one of the very large drawings by Mr. A. B. MITCHELL. There are also examples by Mr. H. O. CRESSWELL, Mr. HARRISON, Mr. E. A. HILL, Mr. CUTLER, Mr. V. T. JONES, Mr. W. COLES, Mr. H. FIELD, Mr. B. CHAMPNEYS, Mr. A. VIGERS, Mr. GUY DAWBER, Mr. REDFERN, Mr. BEDINGFIELD, Mr. M. H. B. SCOTT, Mr. W. T. WALKER, Mr. E. P. WARREN, Mr. A. GIBSON, Mr. A. N. PRENTICE, Mr. P. M. HORDER, Messrs. NIVEN & WIGGLESWORTH, Mr. L. J. WILLIAMS, Mr. R. A. BRIGGS, Mr. J. BROOKE, Mr. P. WATERHOUSE and Mr. A. M. POYNTER. They are of a class which can be attained without imposing onerous sacrifices on the owners, and deserve to be prized as homes. The smallest and cheapest reveals an endeavour to avoid the commonplace, while retaining a type that will not be wanting in simplicity.

There are large country houses, such as Welburn Hall, Kirbymoore-side, by Messrs. DEMAINE & BRIERLEY, which, among other effective parts, has an open arcade or approach on one side, laid out on a curved plan; Motcombe, Dorset, and North Mymms, by Messrs. ERNEST GEORGE & PETO, which might be taken for excerpts from "Nash's Mansions"; Ashcroft, by Mr. W. F. UNSWORTH; Culford Hall, which has more of an Italian character than is common now; Athelhampton Hall, with its ancient garden, by Mr. INIGO THOMAS; Endall's Manor, by Mr. BELCHER; the interiors of Hurstbourne, Hants, having elaborate woodwork; Elm Bank, Kettering, by Messrs. GOTCH & SAUNDERS; Abbot's Leigh, by Mr. F. C. LEES; Test Court, Chilbolton, arranged to form three sides of a court, &c. The majority of those mansions may be accepted as English in character and as consistent in details.

The town houses are more varied. The buildings in Norfolk Street and Arundel Street by Mr. JOHN DUNN, in which terra-cotta is largely used, would be more appreciated if placed in wider streets, and they have an air of prosperity that befits them as offices. The proposed new premises in Kingsland, by Mr. C. V. JOHNSON, correspond with other examples in the room in showing strong arching over the shop windows, by means of which the upper storeys will not appear to be carried by a signboard and a sheet of plate-glass. The Conservative Clubhouse, Glasgow, by Mr.

EDIS, is Scottish to a slight extent, for the upper part is not quite so plain as the remainder of the elevation. The houses in the Melbury Road, by Mr. H. RICARDO, have more of the Old Court suburb style about them than many others in the road. Mr. C. F. HAYWARD's row of mansions opposite the British Museum is in red brick, with stone dressings, and the storeys are well adapted for flats. A terrace at Stoke Newington, by Messrs. BOOTH & ANDERSON, we suppose is also intended for several tenants besides the shopkeepers, if we may judge from the proportion of window openings to solid parts. The immense windows seen in the upper floors of Mr. IVOR PRICE's houses in Cannon Street, Dover, we suppose became necessary because the rooms are likely to be used for business purposes. Mr. J. J. STEVENSON's Porches were worth special representation, for modern houses are too often considered to be worth attention only on account of the general effect. Mr. H. HUNTLY GORDON's Offices for the Ocean Accident Guarantee Corporation are almost unique in the exhibition, as they are an adaptation of Gothic, but the windows are ample.

Two of the designs for the buildings in Bath are shown. Mr. BRYDON's additions to the Pump Room are more satisfactory in the interior view, for the pair of façades, with their pediments and columns, appear to be merely stuck on the principal front. Messrs. BAGGALLAY & BRISTOWE's treatment of the great Roman bath is interesting from its Classical character, and the introduction of figures on the piers would increase the effect. The Homœopathic Hospital, by Mr. W. A. PITE, is a plain but well-proportioned brick building, and patients should be grateful for the avoidance of a flight of steps to the entrance. The design for the Walsall Town Hall, by the same architect, we imagine, was not appreciated because of the number of doors which lead to the balcony. The Municipal Buildings, Rotherham, by Mr. LOVELL, has the advantage of distinctly suggesting the different departments. The Public Offices and Technical Institute, Leyton, by Mr. TULLOCH; the Victoria Institute, Worcester, by Messrs. SIMPSON & ALLEN (shown in five views); the Northampton Institute, Clerkenwell, by Mr. MOUNTFORD, are characteristic examples of the buildings that now find favour with committees. A building such as Mr. HORSLEY proposes for the St. Helen's Technical Institute, or that by Mr. JEMMETT for the Darlington Municipal Buildings, runs the risk of not being adequately appreciated. If the Gower Street front of University College, London, can be completed by Professor ROGER SMITH, as it appears in Mr. BREWER's drawing, the dismal street will be improved. Another scheme for improvement is seen in Mr. STATHAM's courageous study for remodelling the front block of the National Gallery by raising and altering the dome and introducing copies of the campaniles of St. Paul's. The gain would, however, be not worth the labour; WILKINS's work cannot be mended, and it is wiser to let it stand as a sort of gauge to determine the progress of architecture in London. The new P. & O. Offices, Leadenhall Street, are an excellent example of Mr. COLLICUTT's town buildings, but we trust the panels under the windows which display the stages of ship-building will not suffer at the hands of mischievous boys. Buildings for education are not numerous. It is interesting to compare the designs for the choir schools of Magdalen College, Oxford, which were prepared by two Associates, Sir A. W. BLOMFIELD and Mr. G. F. BODLEY, and opinions will differ about which is the more successful. Expense apparently was against Mr. BODLEY. The Collegiate Buildings at Ampleforth, by Mr. BERNARD SMITH, and some anonymous co-operator, recall WELBY PUGIN's treatment not only in design but in the manner of getting up the drawing. The premiated design for Harringay Board School, by Mr. BUTLER, corresponds with the normal type for the Metropolis. Mr. E. B. LAMB's small art school is rather quaint, but storeys can be added without much inconvenience. The South-Eastern Agricultural College at Wye, by Mr. P. B. CHAMBERS, is a long low L-shaped building—a sort of continuous cottage that is better adapted for use than a lofty building. Mr. FAIRLEY's drawing of the Board School at Armadale, West Lothian, was lately reproduced in this Journal. Mr. ROBSON's Ashton Grammar School, Dunstable, is a compact block, a chapel-like hall forming the central part.

WATER-COLOUR SOCIETY.

"SUMMER EXHIBITION" may be interpreted as applying not merely to the season, but to the character of the drawings which are now to be seen in the room of the Water-Colour Society. With one or two exceptions everything relating to winter has been kept out, and as the majority of the drawings are of native subjects, the exhibition therefore testifies to the beauty which is still to be seen in England. On that account more delight can be derived from what is presented in the room than from much larger exhibitions.

As in most other places where modern art appears, it becomes evident in the Pall Mall Gallery that the spirit of innovation [is trying to assert itself. There are little

which have taken place. It is no longer supposed that water-colour drawings are cabinet gems which cannot be examined too closely. They have now to assert their power in large rooms or galleries against backgrounds which are deep in colour, and in proximity to *bric-à-brac* of a variety of materials. As a consequence, not only are drawings turned out on a larger scale, but they are manipulated in a manner that will "tell" at a distance. The paper is operated on to an extent that would appear incomprehensible to DAVID COX, and he was supposed to go to extremes in the employment of coarse grounds, and the colours are applied of a thickness that will bear measurement. In any exhibition the experiments which have for object the extension of the art would appear

SUNDOWN AND THISTLEDOWN.—TOM LLOYD.

WHITEHALL.—H. M. MARSHALL.

drawings of flowers which WILLIAM HUNT would have enjoyed, and on the walls, as well as on the screens, there are examples which seem inspired by an old-fashioned spirit. Among the artists who are mentioned by THACKERAY in the article on the Gallery, which appeared half a century ago, there is only one survivor, viz. Mr. G. D. FRIPP, but PROUT, BENTLEY, TAYLOR, CATTERMOLLE, NASH, OAKLEY, WRIGHT and FIELDING would be able to say their influence has not entirely come to an end. Nevertheless, they could hardly help expressing astonishment if they were able to see the extent of the changes

remarkable, but in a gallery where the traditions of a more simple and quiet treatment are respected they become astonishing. Old and new methods are so successfully exemplified, it is not easy to be a partisan of either side.

Roman scenes would now seem to be indispensable in every exhibition. Mr. BULLEID's *Morning Greeting*, a girl asleep on a couch with a child kissing her hair, is tender in spirit. The details of architecture and of the inlaid couch are carefully treated. It is not easy to express marble in water-colours, and the artist has therefore introduced drapery to protect the panels. Red and brown are the dominant

colours. Mr. RADFORD probably comes nearer the reality when in his *Puellula Mala* he represents a little Roman vixen—it may be the child of a slave—who has torn a crimson robe, and does not appear to be contrite for the misdeed when complaint is made against her. The two drawings are more solidly painted than Mr. T. R. WEGUELIN'S *Battle of Flowers*, which is indefinite in detail, and might be only a study for a picture. He has discovered an interesting subject in *Venetian Gold*, which represents the trouble which ladies endured in dying their hair in Venice.

sand from the shore—is one of his happiest compositions. The *Chapel of the Sangreal* is a decorative piece by Sir E. BURNE-JONES; the three knights are attended by three angels, and there are also three angels adoring in the chapel. It is difficult to persist in the production of mystical figures throughout the year without becoming mechanical. It is no wonder that in the drawing before us neither mortal nor celestial beings appear to have any sincerity in their devotion. They are probably more suited for church decoration on that account. The difference between lacka-

MARKET, SEVILLE.—BIRKET FOSTER.

EVENING.—T. R. LAMONT.

The *Canephora*, by Miss PHILLOTT, is a graceful figure of a girl carrying a basket of flowers, who is placed against a wall of coarse masonry, as if to suggest the origin of the caryatids. The *Beadsman*, by Mr. WAINWRIGHT, is another of those large heads of monks he prefers, and shows his usual vigour. Mrs. ALLINGHAM'S *In the Garden* is apparently a portrait, and is preferable to many that are supposed to be more observant of the laws of the art. Mr. J. PARKER'S *Sand for the Floors*—French girls removing

daisical and genuine religious emotion will be apparent from a comparison of the drawing with Mr. HENSHALL'S *Gethsemane*, which is as impressive as any of the ancient versions of the scene. But there is no scope in England for talent which can vivify scripture scenes. If we could imagine Mr. HUGHES'S *Trifles of this Sort* to represent a young member of the Sheffield trade expounding the mysteries of an ill-shaped cruet and "plate" to his bride, without any suspicion of the vulgarity of the theme, the success of the drawing would

be unquestionable, and the technical execution merits the position it has been awarded in the room. But it is an insult to the memory of one of the best beloved of English writers to identify the scene with ELIA and his cousin BRIDGET. CHARLES LAMB was gifted with exquisite taste, and he was not likely to go into raptures over hideous table-knives and other appliances for the dining-table. If Mr. HUGHES condescended to read the essay from which he professes to have taken an extract, he would have found that ELIA, who was no longer young, describes himself and his cousin as rejoicing over a "set of extraordinary old blue china," but he is like the majority of English artists, and cannot conceal the weakness of his knowledge. It may be the picture was ordered by some Sheffield manufacturer, whose productions it represents, and who is eager to see it placed amidst the RUSKIN collection. Mr. GLINDONI'S *A Ward in Chancery* is neither better nor worse than a great many of his drawings, in which probability is sacrificed in order to "make the unskilful laugh." It is a pity so much skill in drawing and in suggesting character is not turned to better account.

There are several pictures in which the figures, although only subservient, are not exactly puppets like those which CLAUDE said he gave away with the landscape. Mr. TOM LLOYD has imparted a touch of pathos to his *Desolate and Oppressed*, although the man and woman, who are tramps, recall other pictures. The figures in *Sundown* and *Thistledown* also are old acquaintances, and so are the river, punt and bank, but the whole is so well put together that, in spite of its bad position, the drawing was among the first to find a purchaser. *Mecca Pilgrims Returning to Cairo* is one of those combinations of Eastern architecture and figures by Mr. CARL HAAG which never become monotonous. The painstaking execution may be considered as out of date by those who admire Mr. A. MELVILLE'S *Tangiers*, which is undoubtedly clever, although the figures are like impressions

on bad blotting-paper of sketches or of figures in a better style, as they appear at an immense distance. Mr. R. W. ALLAN has made a name with similar efforts to express remote appearances, but Mr. MELVILLE'S are on a larger scale. The figures in Mr. BIRKET FOSTER'S *Market* may be strangely like Surrey girls, but how effectively they place themselves in their positions! Neither PHILLIP, LONG nor BURGESS have formed better groups, and the buildings, which are as commonplace as if they were erected by a

County Council, are rendered with a fidelity that must have been painful to a hand that was only accustomed to depict rose-covered cottages. Eighteenth-century formalism has inspired Mr. LAMONT'S *Evening*. If we can accept SHAKESPEARE'S authority, bowling was one of the games in which ladies could take part from the time of RICHARD II.

Landscape is the pursuit of the majority of the members. Mr. H. M. MARSHALL gives views from Dordrecht and Edinburgh, but most of his drawings are, as usual, derived from London. We do not quarrel with him for suggesting that buildings can be elastic at the desire of an artist, but there is no use in suggesting that Sahara would be a region of calm and serene air if compared with a London street. Hereafter it will be supposed that we were enveloped in an atmosphere that was copper-coloured and palpable. Mr. NORTH, A.R.A., in his *And so the ever-running year follows*, recognises that vegetation is not always brown, but Mr. EYRE WALKER is more faithful to the old belief. Mr. W. CALLOW'S *Château d'Amboise* lies rather low,

but he suggests the fine colour of the old masonry. Sir F. POWELL'S *Calm* is a seascape, for which the title is no misnomer. Mr. A. GOODWIN'S *Whitby Abbey* is one of the best views of a favourite subject, but the red light that darts from the sky is so intense that one imagines it must be a sort of symbol of something unknown. Mr. ROOKE'S *Mont St. Michel* shows the noble building above the roofs of the houses, but the contrast is too violent. We prefer it to

INNSBRUCK.—S. J. HODSON.

CHÂTEAU D'AMBOISE.—W. CALLOW.

Mr. A. GOODWIN's view, in which the abbey is seen through blue glasses. Mr. C. GREGORY's *New Winchester* is capital, and more charming than the title suggests. Mr. E. A. GOODALL's *Bay of Naples* is an attractive rendering of a subject that is almost hackneyed. Mr. HENRY's *Head Wind* will make many visitors long to escape from town, for the waves are not appalling to landsmen. Mr. HODSON's architectural scenes grow in interest. This year he gives two drawings of Innsbruck, one a street view, which is taken in the right direction; the other the so-called Maximilian tomb, with the rows of princes of the House of HAPSBURG. Numerous as are the views of Niagara, it may be doubted whether one representing the place "after long drought" was drawn before Mr. A. W. HUNT made the attempt. Mr. S. P. JACKSON has an impressive view of *Bamborough Castle*. Mr. W. CRANE has among his drawings one showing the *Approach to the Chapter-house, Wells*, which does not do justice to the peculiar steps. There are many other drawings which are deserving of the attention of visitors, and on the whole the exhibition can be considered as having more than the average amount of interesting works.

THE MOROSINI PALACE, VENICE.

THE palace in the Campo San Stefano which belonged to the naval commander and doge, Francesco Morosini, who lived in the seventeenth century, has been the subject of litigation. According to the *Scotsman*, the last heir in a direct line died in 1887 intestate. The claims of twenty-one heirs, chiefly Germans and Hungarians (for the Morosinis had married into the royal house of Hungary), to succeed to the palace and its precious contents were, after a long law suit, admitted. In 1889 they threatened to bring the property to the hammer, whilst the syndic of Venice and the other authorities were anxious to secure it, so as to preserve it intact as a specimen of a doge's house, and a show-place which would add still further to the attractions of their unique city. The city is not rich enough to buy it, but the authorities have succeeded in holding from off it the sacrilegious hands of the spoilers during these past four years. A month ago it seemed as if they were to be beaten. At last the heirs were to have their booty and the palace was to be broken up. A paragraph has been going the round of some of the English journals that June would bring round the auction day, and there was foundation for the report. However, its hour of peril has been its hour of victory. Count Morosini, who is descended from another branch of the family, has stepped into the breach. He has bought the palace and all its contents. At present he lives in the well-known palace on the Grand Canal, the Ca d'Oro. That palace has just been bought by Baron Franchetti. Probably he intends to live in it himself, and Count Morosini will flit to his newly-bought property in Campo San Stefano. It is understood he has already agreed to the request of the municipality, and will open the unique palace on certain days to the inspection of visitors, so that the travelling public as well as Venice may be congratulated on the happy termination of the question of this old doge's palace, which has remained to this day exactly as Peloponnesiacs left it. It is crammed full from floor to ceiling of all things rich and rare—things having an intrinsic value, but in many cases a greater historic one. Such, for example, are the *fanales*, or lanterns, hung on the walls of the great entrance-hall, which were taken from the ships Morosini commanded, and which show in order every grade of command he held, from that of a petty officer to commander of the fleet. Spoils of his Turkish wars decorate every room, and pictures by Titian and by other masters, and by Longhi, the Hogarth of Venice.

TESSERÆ.

Conventional and Imitative Art.

DECORATIVE art, as exhibited in its latest examples—such as the artistic cretonnes, the delicate wall-papers and encaustic tiles which the new æsthetic revival is making familiar to us all—depends for its effect almost entirely on immediate sensuous gratifications, though these are often of a comparatively high order. It gives us abundant visual stimulation by its pure and exquisite colours harmoniously combined, by its pleasant alternations of light and shade, by its novel tints curiously sought out and effectively disposed. It yields us the highest pleasure of form in its graceful, flowing and continuous curves; in its lissom sprays of straggling foliage, which nevertheless lead on the eyes unresistingly through their most natural muscular sweep; and in its symmetrical disposition of fruit and flower and animal form. But in its purest and most evolved types it never attempts directly to imitate nature. At

most, it takes a hint from some natural object, which it conventionalises, as we say—that is, renders in symmetrical arrangement and artificial colouring. Its sole object is to give us the largest possible amount of sensuous pleasure by means of colour, simple or combined; and of form, sinuous or symmetrical. If it imitates nature, it does so only incidentally, and it owes nothing to the accuracy of the imitation. Imitative art, on the other hand, may incidentally afford us similar sensuous pleasures, but in its most developed types it has shown a tendency to rely more and more upon the exclusively intellectual and emotional factors of æsthetic feeling. It takes some object in external nature, and endeavours to represent it on a plane surface, in colour, in chiaroscuro and in perspective. It tries to set the scene before our eyes as nearly as possible in its true lineaments, its actual relations, its total visible aspect. The whole growth of artistic technique has been the perfectioning of this process. From the single plane of the Egyptians and the floating background of the Chinese, art has advanced to the scientific perspective of the present European style. From the primary colours of the savage and the brilliant hues of the Mediæval artists, it has arrived at the comparatively sombre delineations of modern landscape painters. In doing so it has become from day to day less decorative and more imitative. It has to a great extent given up the attempt to please us by bright primaries, by gilding, by symmetrical arrangement, by curves and wave-lines not to be found in nature. It has largely abandoned the purely sensuous gratifications, except so far as these may be really found in the objects which it copies; and it has learned to rely on the intellectual pleasure of skilful imitation, combined to a slight extent with plot-interest and sundry complex emotional feelings.

Lysippus the Sculptor.

Lysippus was a native of the city of Sicyon, in the Peloponnesus, and flourished about 324 B.C. He was at first a worker in brass, but afterwards devoted himself to statuary, studying nature, by the advice of Eupompus, rather than following the manner of any master. He excelled all those who had preceded him in the nicety of any individual parts, and more particularly in the beauty of the hair. He lessened the size of the head, which had been exaggerated by the ancient sculptors, and made the body more slim so as to increase the appearance of the height. He used to say that former sculptors represented men as they were, whilst he made them as they appeared to be. His reputation was such that his name was included in the famous edict published by Alexander, when he conferred on Apelles the sole right of painting his form, on Lysippus that of executing it in bronze, and on Pyrgoteles that of engraving it on precious stones. He is said (Plin. xxxiv. 7) to have produced 1,500 works of art, any one of which was sufficient to stamp him as a man of talent. Of these we can only mention a few of the most celebrated. There was one at Rome, the removal of which from the Baths of Agrippa to the palace of the emperor, by order of Tiberius, had nearly caused a sedition. The populace clamoured for its being replaced, and Tiberius did not deem it prudent to deny their request. It was a statue called Apoxyomenos, representing, as its name implies, a man scraping himself in the bath with a strigilis, an instrument to clean the body of the particles of sweat. He executed many statues of Alexander, representing him at different periods of his life; and he so managed that a slight bend of the head, for which Alexander was remarkable, became rather a beauty than a deformity. One of these statues was so much admired by Nero that he caused it to be covered with gold, to the great grief of all true lovers of the art of sculpture. He executed a very fine bronze statue of Cupid with a bow, for the inhabitants of Thespis; also equestrian statues of twenty-five Macedonians who fell at the passage of the Granicus, and which Metellus caused to be transported to Rome. It has been supposed, though without any clear proof, that the celebrated horses of Venice formed part of this group. There is a statue of Hercules in the Palazzo Pitti at Florence, which bears his name, and has in every respect a strong resemblance to the Farnese Hercules, excepting the position of the legs. This likewise has made it be supposed that the statue of the Palazzo Pitti is a copy of the Hercules of Lysippus, and that the Farnese is an imitation on which Glycon thought he might engrave his name, on account of the change he had made in its position. Lysippus had as pupils his own sons, Dahippus, Bedas and Euthycrates (Plin. xxxiv. 8).

Greek Vases.

Greek vases may be divided into five periods, assigning approximate dates of antiquity, as follows:—First archaic period, previous to the eighth century B.C.; second archaic period, from the eighth to the seventh B.C.; third archaic period, from the seventh to the sixth B.C.; fourth, the finest period, from the sixth to the fourth B.C.; fifth, the decadence, from the fourth to the second B.C. The peculiar characteristics of each period are as follows:—The first archaic period: of these, the earliest

specimens of Greek fictile art, most are discovered at Athens, Corinth, Melos, Camirus in Rhodes, and Etruria. They are very rude, painted in reddish brown or black, on ash-coloured ground, with chevrons, concentric circles, stars, &c., and primitive representations of men and animals. The vases of the second archaic period are abundantly supplied from Camirus in Rhodes, as well as other parts of Greece. They show a great improvement in the drawing of the figures; they are usually of cream-coloured clay, painted with crimson and white, and red on black, the details being scratched with a point, the style of ornamentation being two or more rows of animals (real or imaginary), of birds, harpies, sphinxes, &c. In the third archaic period are found the most valuable Greek vases, of a more artistic character than those which precede it. The figures are painted in black, on a red ground, and the designs are confined to a square tablet between the two handles, the rest of the vase being painted a lustrous black. Mythological and heroic subjects are now introduced, and complicated groups of figures, chariots and occasionally inscriptions. The fourth is the best period of Greek art. These vases may be especially distinguished by the design being left red, the ground filled in with black, and the details of costume, features and anatomical delineations produced by black lines. Sometimes are found black figures on red and red figures on black on the same vase. This may be considered a transition from the archaic to the more artistic style. The fine vases of Nola may also be attributed to this period. The fifth period may be called the decadence, and dates from the accession of Alexander the Great, B.C. 336 to B.C. 186, when it is presumed the fabrication of painted vases altogether ceased, shortly after the edict of the Roman senate against the celebration of the bacchanalian festivals in that year.

Chinese Bricks.

It is certainly not for want of materials that the Chinese have not already acquired a fame for architecture, as probably no country in the world could show a greater amount of building or could surpass it in abundance and excellence of material fit for building purposes, which are similar to those commonly used by other nations, namely, bricks, timber and hewn stones; of the first named there are several descriptions, each being suited to a particular purpose; for instance, to construct massive walls such as the walls of their cities bricks a cubit in length and a span wide are not uncommonly used, while the walls of ordinary houses are built of bricks of much smaller dimensions, some of them approaching the ordinary European standard. The difference in the form and size of these bricks is very variable—some are flat, being about 10 inches long, 5 inches wide and 1 inch in thickness; others are 14 inches wide and 3 inches thick, while those in most common use are about 7 inches in length, 3 inches in thickness and 2 inches in width. Besides bricks, curved and plane brick tiles are used in roofing common buildings. In Pekin the palaces and some of the temple buildings are tiled with glazed yellow tiles, having a very brilliant effect in the sunshine. Flat tiles are used in flooring their courtyards and houses; sometimes they are met with as large as 2 feet square and are exceedingly hard and compact in texture. All bricks and tiles made by the Chinese are of a dull grey colour, and hence the sombre grey tint of walls and buildings throughout the country. The fuel employed by the Chinese brickmakers is straw and not coal. Nevertheless Chinese bricks are very durable, hard and compact in structure. Their colour is not owing to any peculiarity of the soil of the alluvial plains throughout China, which is not very well adapted for brickmaking purposes, on account of containing lime; this is proved by the red tint bricks assume when baked in brick ovens constructed after the European model and heated by coal. Chinese bricks are invariably marked with a stamp, and some of the very ancient ones found in the structure of their temples and other buildings bear the date, the place of their manufacture and more frequently the name of the building they are intended for, in this respect reminding us of the marks on the ancient Egyptian bricks. Being of a very fine even texture, bricks and tiles are easily planed so as to join very closely. They are also easily sculptured to form the great variety of ornamental work found over their doors or inner apartment walls.

Notre Dame at Mantes.

The vaulting is with oblique groins, as at Beauvais. Generally with oblique groining, the piers are usually alternately larger and smaller. In this church the direct arch between the greater piers seems to be formed on an equilateral triangle, or nearly so, rising on the capitals of the shafts; but on the smaller piers the perpendicular line is continued considerably above the capital, and the direct arch between them is consequently very obtuse. Perhaps it was this whim which attracted the admiration of Soufflot, who is said to have been lost in astonishment at the *hardiesse* of the vaulting, although the nave is only 34 feet wide. The boldness of the architect is, however, sufficiently conspicuous in other respects, for the piers of the chevet are only 1 foot 11 inches in diameter, to

support a vaulting which rises 102 feet 6 inches (English measure) from the ground. One of them is consequently crippled, and has been banded and supported on every side with iron. Gabriel, one of the companions of Soufflot, in his examination of this church, contends that the six columns of the chevet might all be cut away, and that, nevertheless, by the scientific disposition of the stones, the upper part and the vaulting would remain secure. This, indeed, would be something wonderful.

A Mayo Gable.

The accompanying woodcut introduces us to the modes in which ancient builders in Ireland applied stone different to what is attempted at the present day. It represents a portion of an abbey tower in the county of Mayo, constructed with Moyne stone. The gable shown on the

side of the tower is formed by an increase in thickness of the walling of about 6 inches, and on the outline of the gable a semicircular channel is formed with carefully walled stone; on this the ends of the slates rested, and instead of having lead, now usually employed, or plaster, to prevent the water from getting between the wall and the end of the abutting roof, the water was allowed to find its way into the channel or gutter which the slates or other covering overlapped—a mode of construction both ingenious and model.

Decay of Stone.

A cubic foot of toadstone has different weights, according as the stone is more or less decayed, that which is most decayed being the lightest. There is a stratum of bluish grey ragstone in Westmoreland, which lies under the limestone; large cobbles of this sort of stone which are exposed to the air are decayed to a certain depth from the surface, whilst the inward part seems entire; a cubic foot of the outward part of one of these stones weighed 2,378 ozs., when the inward part of the same stone weighed 2,603 ozs. to the cubic foot. This ragstone is very hard, but the same phenomenon may be noticed in a stone still harder. The Cambridgeshire black flint weighs 2,592 ozs. to the cubic foot; the same flint, being in part decayed and become externally white, though black within, weighed 2,414 ozs., and when become wholly white 2,400 ozs. to the cubic foot; the general reason of this seems to be that the pores of the decayed body are augmented. Kirwan has well explained the manner in which nature operates in decomposing stones. "Flints, jaspers, petrosilex, felspar, granites, lavas and ferruginous stones have frequently been said to be decomposed by the air, and the observations of Mr. Greville and Sir W. Hamilton have removed every doubt I entertained on this head. With regard to ferruginous stones in which the calx of iron is not much dephlogisticated this decomposition is easily understood, for this calx gradually becomes more dephlogisticated by the action of water and air, attracts water and fixed air and loses its adherence with the silicious or other stony particles; this is seen to happen to basalts, toadstone, ferruginous limestones, &c. In other stones this decomposition may arise from their containing calcareous earth in a caustic state or manganese, for these will gradually attract water and fixed air and then swell, burst and loosen the whole texture of the stone, as we see happen to bricks that contain lime. Thus also glass is decomposed by long exposure to the air, the alkali attracting water and aerial acid. Mortar, on the contrary, hardens by long exposure to the air, because, though the aerial acid be attracted, yet a great part of the water exhales." The changes produced by the long exposure of bodies to the air, and the causes of them, deserve a more minute investigation than has hitherto been bestowed on the subject.

Public Taste.

The taste of a people, which is to art what public opinion is to legislation, is formed, like public opinion, by habitual social intercourse and collision. The more men are brought together to converse and discuss, the more the principles of a general national taste will become both diffused and refined. Less to their climate, to their scenery, to their own beauty of form, than to their own social habits and preference of the public to the domestic life, did the Athenians and the Grecian republics generally owe that wonderful susceptibility to the beautiful and harmonious which distinguishes them above all nations, ancient or modern. Solitude may exalt the genius of a man, but communion alone can refine the taste of a people.

NOTES AND COMMENTS.

WHEN we find in four months REMBRANDT, WEDGWOOD, BASTIEN-LEPAGE, and the buildings and history of Malta are treated, it will be evident that the "Portfolio Monographs" (SEELEY & CO., Limited) will be as varied as art itself. The latest part, by Mrs. ADY, is devoted to the French painter who in 1876 was contending for the Prix de Rome, and before the end of 1884 was lying in the graveyard of his native village, Damvillers. A life that was so glorious and so brief would excite the sympathy of the sternest critic, and it was one which must appeal to every sensitive woman. Mrs. ADY has written about the artist with a tenderness that befits the subject. BASTIEN-LEPAGE was a type of the earnest artist. The son of peasants who wished to see him happy in some humble Government post in their district, he could not resist the desire to become a painter. Fortunately, he was able to secure a sortership in the Paris Post Office, and his spare hours he offered to painting. To make the most of them he concentrated his powers on his studies, and the habit remained with him. When he made a name he allowed himself little relaxation. As the late ALBERT WOLFF wrote, "His fellow-artists saw him scarcely. To some of them he was a peasant who had yet to be civilised; to others he was simply a bear. He lived by himself, and was supposed to be unsocial; he spoke but little, and was said to be proud. He appeared to despise talk, or at least he was not anxious to refute his critics by speech, and in this spirit he acted to the end." For a time BASTIEN-LEPAGE was compelled to follow the prescribed academic course, but his soul was in revolt against it, and after two failures to gain the Prix de Rome he allowed his inclinations to guide him, and he painted what he saw, instead of endeavouring to imitate ancient artists. Realism was in the air, and he became one of its most faithful exponents. If he were accustomed to Paris ways he might have produced Impressionist vagaries, but his familiarity with country scenes saved him. He produced pictures which were as faithful as MILLET'S, without being gloomy. His *Joan of Arc* suggested how easily he could utilise the peasants to depict the deepest emotions. The fidelity which is seen in his pictures of lowly life qualified him to be one of the greatest of portraitists. All sides of his genius are described by Mrs. ADY, and it is needless to say the illustrations of BASTIEN-LEPAGE'S works are numerous and successful.

AN edition, corrected to 1893, of Mr. ELLIS MARS-LAND'S "Rules and Regulations affecting Building Operations in the Administrative County of London" has been published by Mr. B. T. BATSFORD. It contains not only the by-laws of the County Council under various Acts, but the special regulations which are enforced in the City of London, in the various vestries and district boards. The book is therefore a guide which will be helpful not only to architects and builders, but to all who have any concern about houses in the Metropolis. The size of the book adapts it for carrying in the pocket, and from the arrangement the information that is sought can be found without loss of time.

ONE of the grievances of owners of houses in new districts arises from the demands for making-up roads adjoining their property. The majority of people have a notion that streets and roads are paid for out of some general fund in all cases, and when they receive an order to pay what seems to be a preposterous amount, they become embittered towards authority. It may be allowed it does not seem to be equitable that an individual who happens to own a corner plot should have to pay for two stretches of footway which are devoted to public use. It is harder still when a man who may own nothing that runs on wheels is mulcted for the cost of a carriageway. A case of the latter kind was before the judges in the Queen's Bench Division on Wednesday. The Corporation of Derby having absorbed a suburban district, gave the usual notice about the carriageways as well as the footways being taken over. In due course the sum of 15*l.* 10*s.* was claimed from the frontager, who became the defendant in the action. As he did not pay he was summoned. He admitted his liability for so much of the expense as related to the footway, but maintained he

was not bound to pay for the carriageway. The magistrates agreed with him, and the Corporation therefore appealed. It is remarkable that Mr. Justice CHARLES and Mr. Justice COLLINS, who heard the appeal, considered that notices which included the expense of the carriageway ought not to have been sent, yet they gave judgment for the Corporation, and the case was sent back to the magistrates. The reason for that course was that the defendant had not adopted the proper procedure. When before the magistrates it was for him to show that he was not the frontager, or that he had no premises fronting the street, or any other defence which offered an answer as to the whole. But the defendant was not able to offer such an answer, and had to admit that he was liable as to part. It became, then, a question not of jurisdiction, but of amount, and could only be disputed by a notice under section 257 of the Municipal Corporations Act, the time for which had passed. It is hard on the defendant and his neighbours to have to sustain a contest for which they have to pay the expenses of both sides. Would it not be wiser for the Corporation of Derby to admit that in trying to keep down the rates they were rather hard on the inhabitants of the Letchurch suburb, and come to terms without further litigation?

IT is difficult to understand the action of the Liverpool Corporation in dealing with the proposed Northern Hospital. The DAVID LEWIS trustees, having the disposal of an immense sum of money, arranged to expend a part of it on a hospital "which would be unequalled and unsurpassed by any hospital in the world." But before entering upon the arrangements the trustees wish to have an adequate site. The Corporation are willing to grant a piece of ground in Gibraltar Street, containing 360 square yards, and a strip of land between the site of the present hospital and the Lancashire and Yorkshire Railway, containing 1,545 square yards, besides contributing 15,000*l.* towards the cost of construction. The trustees consider the ground offered is of insufficient area. They say a proper site will cost about 75,000*l.*, and they ask the Corporation to contribute one-third of that amount. An amendment was proposed at the meeting of the Council on Wednesday to the effect that the Corporation grant should be increased to 25,000*l.* When the voting took place there were twenty-six given on each side, and the Deputy Lord Mayor gave his casting vote against the amendment. Eventually it was decided to refer the subject once more to the finance committee, when it is to be hoped wiser counsels will prevail.

THE Council of the Bristol and Gloucestershire Archaeological Society have proposed that a photographic survey of the county be commenced under the auspices of the Society, that an executive committee be appointed to draw up a scheme for carrying out such a survey, and that such committee consist of three delegates from each photographic society in the county, and as many members of that Society as should be equal in number to all the other representatives. When the survey was suggested to the Council it was contemplated that it should be confined to archæology, and such a survey only would be inaugurated by the Society. If, however, it was generally wished that the survey should be extended to other studies, such as natural history, geology, botany, &c., representatives of the various societies and clubs connected with such studies would naturally be invited to join the executive committee, with a view to drawing up rules for the scheme thus enlarged. At the meeting of the Society which was held last week, Mr. H. S. PEARSON was able to give information concerning the progress of the photographic survey of Warwickshire. In 1829 the subject was first brought before the Birmingham Photographic Association. In 1890 a survey council was appointed, and since that time no fewer than 2,100 permanent photographs of archæological interest in the county have been taken. Two public exhibitions of these pictures have been held, and 1,600 of the prints have been presented to the public library for reference. The remaining portion of the photographs will also find their way to the same building. Copies of portraits were lately included in the work of the survey. From the success attained in Warwickshire it might be supposed that similar organisations would be established throughout the country, but the counties are only slowly adopting the idea.

ILLUSTRATIONS.

THE WEIRD LADY.

THE illustration is reproduced from a large drawing by Mr. LOUIS FAIRFAX-MUCKLEY, which was exhibited in the Royal Academy in 1890. The scene is taken from one of the late CHARLES KINGSLEY's poems. It relates to HAROLD the Earl, who for a time was enthralled by the Weird Lady in a charmed castle over the sea. At last he was able to return to his own country:—

Earl Harold came to his castle wall;
The gate was burnt with fire;
Roof and rafter were fallen down,
The folks were strangers all in the town,
And strangers all in the shire.

Then he went to a nunnery where the burial service was being chanted for one of the sisters—his own lady—who died for the love of a traitor knight:—

He stayed the corpse beside the grave;
"A sign! a sign!" quod he,
"Mary Mother, who rulest heaven,
Send me a sign if I be forgiven
By the woman who so loved me."
A white dove out of the coffin flew;
Earl Harold's mouth it kist;
He fell on his face, wherever he stood,
And the white dove carried his soul to God
Or ever the bearers wist.

The artist has represented the scene in the last verse with adequate dramatic power, and it will be admitted that the task was not easy.

WAREHOUSE, BIRMINGHAM.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on Friday evening, Mr. E. W. Mountford, president, in the chair. The house list for the ensuing session, as nominated by the Committee, was read out, Mr. E. W. Mountford being nominated as president, and Mr. Booth and Mr. Earle as vice-presidents.

In the absence of Mr. R. A. Briggs, who was unable to attend, Mr. GOLDSMITH, hon. secretary, read the following paper on

Modern House Planning.

When I began to consider what I should tell you about house planning, its difficulties and what to plan and what to avoid, I found that it would be impossible to confine myself entirely to the plans, as the elevations, sections, details and, indeed, the whole building should grow in your head as you plan. Nothing should be left to chance, and as you plan your building you must have in your mind's eye not the lines you put on the paper, but the building itself as it will look when finished, with the lights and shadows, doors and windows, full lights and cross lights, and indeed the whole building finished and furnished and ready for occupation.

I have always found that the easiest method to start on planning a building is to draw it out—plans, elevation, sections and perspective to a very tiny scale, such as 32 feet to the inch, and I generally make these sketches in an ordinary architect's pocket-book, with the paper lined in squares. One can erase and alter very easily and quickly with such a small scale. Then when I have the whole thing thought out I begin to work out the building to eighth scale, when I, of course, put in all the details of the plan, &c.

After the very interesting and deeply instructive paper which our learned professor—Professor Kerr—has read in another place on "Town House Planning," and to which I have but little to add, I will confine my remarks to country and suburban house planning, particularly as I have had more experience in that class of house.

Well, now, let us start at the beginning. A gentleman comes to one of us (I wish these gentlemen came more frequently) and wants us to design him a house. He has bought a plot of land which he considers admirable—beautiful views, near a station, gravel soil, water and gas laid on, and the land having a gradual slope to the south. Nothing could be better; an ideal site in every way. Well, what sort of a house does he want? what accommodation? what does he like? and last, though not least, how much will he spend? He answers these questions, and he probably impresses us with some point he considers most important—some crank, such an one as I remember a client once had when he came to me, and, in telling me what his requirements were, impressed upon me most seriously that he did not want any licentious curves about his

house. Well, I did not want to give him any such wicked things; but I saw he had been reading Ruskin, which is a very good thing for all of us to do.

I never like a client to go too closely into the plan of the accommodation, as it is liable to hamper one and influence one too much in looking impartially at the proper planning required. As long as a client gives me roughly the sizes of the rooms and their number, and generalises about their position, I am happy. One must, of course, "draw out" our client as to the style of the house he wants. Does he like the old manor-house style, with mullions half timber-work, or does he want sash-windows? His answer will be the "cue" to the whole building. If he likes mullion windows, tiled roofs, half timber-work and lead lights, I know what he wants; but if, on the other hand, he says, "Oh, sash windows, of course, and good square rooms; none of your tit-bits and pokey windows and corners," then I know my gentleman, and eighteenth century shall be his portion.

We have now a basis to go on, and we will take the house of the manor-house style first, although the general arrangements of the plan would not be affected even if we took the house with the square rooms first, as I shall presently show.

We will say our client wants a drawing-room, dining-room, library, hall and kitchen offices on the ground floor, and about five or six bedrooms, bath-room, &c., on the first floor. We go down and see the land our friend has bought, and note on the plan of the ground the direction of the views, the falls in the ground, and the proposed position of the gardens, tennis-court, carriage-way, &c. And here I would interpolate that the public must be taught that the general arrangement of the gardens is distinctly an architect's duty. Why people should think that an architect's work stops short at the house I can never imagine. The public expect us to design the mantelpieces, panelings, &c., in a house, and then, for no earthly reason that I can see, they wish us to hand over the finishings and furnishings of the house to some firm of decorators, and the garden, which is the setting and frame to the house, to the landscape gardener, so that he may work his sweet will in designing curlywig paths and flower-beds in the shape of pears, sausages, or any other atrocity that commends itself to his "fuzzy-wuzzy" brain. However, I hope that by degrees the public will understand that it is as much the duty of an architect to arrange the gardens and furnishings as it is for a painter to choose the frame for his picture. But to return to our plan, and to what nearly everyone will take our advice about, and that is the position of the house.

Where it is possible, and I have generally found it so, it is best that the entrance front, with carriage drive, should be towards the north, so as to allow the garden front to be towards the south, in which front you will have your windows to the drawing-room, and to as many of the other reception-rooms as you can. I would here, however, mention that it is never advisable to place your house directly north and south. It should be "tipped up," as it were, on plan, either towards the north-east angle or towards the north-west angle, so as to allow the sun to glint, at one part of the day, on the north side. The side of a house which never sees the sun is sure to be cold, and to cause the rooms to be cold also and cheerless. My experience is that, in the East of England, you should "tip up" your house on the north-west angle, and in the West of England on the north-east angle, and then, when possible, arrange a belt of trees in the direction of the "tip" to shelter the house from the gales, which in the East of England would come from the east in most cases, and in the West of England from the west, as these heavy gales generally come from the sea. I have often noticed this small thing, which will show that we architects must have our eyes everywhere. In the East of England the trees slope to the west, whilst in the West of England they slope to the east, showing plainly from what quarter the heavy gales come. Therefore, when you are going to build a house in a new (to you) locality, see which way the trees slope and "look out for squalls," because on that side you must arrange there shall be the fewest number of windows, and mind you see that your walls are prepared for the squalls. Well, now as to the disposition of the rooms.

We start with our entrance porch and vestibule, and do not cramp them. There should always be a covered porch to a country house, so that callers may be under cover whilst the servant is answering the bell, and it protects also the entrance door. There should also be a vestibule with folding doors to prevent the draught from the front door coming into the hall. In porches I have often noticed architects put seats, but I always think this is a work of supererogation, as I have never heard of callers at the present day being so tired that they could not wait till they were ushered into the house, and there are usually better positions to be found for seats for the inmates of the house. The details of the porch, vestibule and hall should not be meagre. They are, as it were, the frontispiece to the house, and a good impression on entering should always be contrived. A speculative builder, whose name I dare say many of you would know if I mentioned it, who had

made his pile on rather small-class houses, was once asked how he had been so successful, and his reply was:—"Well, yer see, I always put a Corinthian cornice in the front portercio." We do not want to copy our friend exactly, but, without being snobbish, we can make our entrance look inviting. "Welcome the coming and speed the parting guest."

I always try and arrange that the hall can be used, if desired, as a room, and it is also very economical planning. And if you put it in the middle of the plan you can have nearly all your rooms opening into it and so save passages. Brillassavarin said, "A dinner without cheese is like a pretty woman with only one eye." Well, I think a house without a good hall is like a woman with no eyes at all. And remember that passages, except for the purpose of giving access to rooms, are all waste space. The problem therefore is to do away with as much passage space as possible. "A passage saved is a room gained," we may say. In the hall at one end you can put a bow window, and near it the fireplace, with a cosy seat, well out of the draught, and at the other end of the hall there would be the entrance and vestibule above referred to. The front door should not be far from the pantry and kitchen, so that the servant will not have far to come in answering the bell. Either in the hall, or just off of it, the principal staircase should be placed, and if possible it should be in such a position that people either going up or coming down the stairs are not in full view of the entrance door. Very effective features can be made of a staircase like this, as may be seen from the designs of many architects I could name. As a rule never cramp the size of your staircase window.

Now let us take the pantry. The pantry must be near the kitchen, and also near the dining-room. And as we do not want to know directly we come into the house in the evening what we are going to have for dinner, nor to let anyone who may happen to come into the house know that the dinner we are going to have will be stewed steak and onions, the kitchen must be shut off by a lobby. What easier thing than to make this lobby into a serving-lobby, with a sliding hatch and double doors? This therefore means that the dining-room must be next this lobby, and thus we get the position of the dining-room. Again, as most people think of themselves first, and as we have not got so far in England as to put our servants in better positions than ourselves, what more natural than that we should put the dining-room towards the south, and the pantry and, if necessary, the kitchen towards the north?

Now then about the kitchen offices, and I fancy some one says, "But you have said nothing about the drawing-room and library." "Quite true, my friend, I haven't." But if you are designing a house for a gentleman, and that gentleman has a wife who is a housewife, woe betide the architect who has not arranged the kitchen offices properly. I remember once designing a house for a lady, and taking the sketches to her, and before she had even seen the plans she said, "Where have you put the housemaid's closet?" Luckily, I had not forgotten it, and had put it in a proper position, but believe me these little (apparently little) matters are the soul of a good plan. In the kitchen, consider seriously this point, the position of the range, so that it (1) shall have a good light on it, that the cook can see into her pots and pans, and (2) that it shall be so placed that the smells can be taken up into a ventilator and not wafted through the serving-lobby into the house. A serving-lobby will prevent a part of the smells coming into the house, but care should be taken to prevent them getting even into the serving-lobby. My experience is that the best place for the range is opposite the door leading to the serving-lobby. The scullery will, of course, be immediately next the kitchen, with direct communication. Then north of the scullery you will place your larder. The position of the larder is important. It must face the north. As Napoleon's answer, during his Russian campaign, to his officers when they were continually questioning him, was always the same, "North," so you in your planning campaigns must remember "larders north." Some architects put their larders with communication from the kitchen, but I think the communication is much better from the scullery. Kitchens get hot, and hot air coming through into the larder is not a good thing for the food placed there. Larders should have lots of ventilation, and I fancy the mistake nowadays is that the architects make the windows too small. I think a larder window should never be smaller than 3 feet by 1 foot 6 inches, and it should have a sheet of perforated zinc instead of glass. Directly out of the scullery, or immediately next it, the coal-cellar and servants' water-closet should be placed. I think the best arrangement for access to these is to have a covered way. You can, of course, let them open into the scullery, but I think it is better they should have their entrances into the kitchen yard or court. It is a much cleaner and sweeter arrangement. To your scullery you will probably have your tradesmen's entrance; arrange this so that the tradesmen need not pass the servants' water-closet. As to wine-cellars, I fear they do not receive the attention they deserve. People do not, I fancy, "lay down"

wine like their grandfathers used to, or else they arrange that their wine merchants keep it for them. Anyhow, my experience has been that only quite small wine-cellars are required, and in most cases they have been kept for economical reasons (generally to save the expense of excavation) on the ground-floor. This is not a bad arrangement if you put hollow walls all round them, and the iron bins you can buy now allow for a large quantity of wine to be stowed in a very small compass.

We will now go back to the hall, and in passing through it we must consider the ground-floor water-closet and lavatory. In every fair-sized house there should be these apartments arranged on the ground floor, and they are difficult apartments to arrange, as they should be out of the way, and at the same time easy of access and easy to find without showing too apparently what they are. Where I often place them is under the landing and stairs, and if the walls are of brick and the ceiling pugged and plastered, I do not think that any inconvenience is likely to arise from this arrangement. Where the mistake has so often been made is to put only 1½-inch or 2-inch partitions to them, but if you put 4½-inch brick walls in cement to them, I do not think it possible that anyone will herald his presence there to the whole household when using the flushing cistern, which, as we know, certainly rings out its clarion note in a somewhat clear and aggressive manner.

Let us, however, pass on to the reception-rooms. We have already decided the position of the dining-room—at one end of the hall, not far from the entrance vestibule, which position was tied by the position of the pantry. A dining-room should be a parallelogram on plan, and it should not be too much cut up with bays and oriels, &c. These are for the drawing-room. The great points to consider in a dining-room are:—(1) That it shall be wide enough for the servants to get easily round the table when the people are seated; (2) that the sideboard shall be close to the serving-lobby and door; (3) that the fireplace shall be far enough away from the table that the persons seated at table shall not be roasted during meals (an angle-nook fireplace will obviate this in a narrow room); and (4) that if the window is at the end of the room and behind the end of the table, it shall not have a light in the middle, so that the host or hostess, or whoever is sitting at the end of the table, will be eating in comparative darkness, and, like the lady in Gilbert's opera, "might very well be taken for forty-two in the dusk with the light behind her." If you must have a window at the end of the dining-room, put a mullion in the middle of it, if a mullioned window, or put two windows with a pier in the middle, and then contrive a window in the side wall, we will say towards the east, to get the morning sun. I think the best arrangement, however, for lighting a dining-room is to put the windows on the long side of the wall and an extra subsidiary window in the end wall. Then your hostess will eat in comfort and bless you, her architect, that you have with true gallantry considered not only her comfort, but the proper setting to her charms.

Well, now we come to the drawing-room. This, with the library, will probably be on the opposite side of the hall to the dining-room, and this is not a bad arrangement. A dining-room, after a meal has been served in it, ought to be aired, and it is not agreeable for people going in or coming out of the drawing-room to be running up against the servants either laying or clearing away the lunch or dinner "things." Besides, we still keep up the old fashion of going in to dinner in procession. Alas! not many old fashions are kept up nowadays, so let us preserve those we can; and the procession across the hall is a pretty sight, and reminds one of what the polonaise or the minuet used to be.

The position of the drawing-room and library will probably be south and west. Perhaps, too, the library will have a window towards the north. It would, however, be better to keep the window towards the west. The drawing-room can well face the west as well as south, so as to get the sun before setting; and as a rule the drawing-room is not much used before the afternoon. In the drawing-room you can show off all your little tit-bits, bows, oriels, bays, seats, &c. A drawing-room need not be, and is generally better for not being, a plain parallelogram. An L-shaped room is always cosier for a sitting-room, and besides, a room of this shape can be much more prettily furnished. If you cannot arrange the L-shape, throw out a large bow window at one end or on one side, near the end of the room. A drawing-room may have many windows, only remember that there should be always a part of the room near the fireplace which will be well out of any draught from any window or door. The library will be probably next the drawing-room, and bear in mind that it will be necessary to arrange your windows and doors so that book-cases may be fitted up round the room. If your client's wife is a woman who has much "society," and gives dances, &c., you should arrange your library so that, by having sliding doors in the wall between the library and drawing-room, she can throw the two rooms into one, and make one big room for dances. In planning the drawing-room and library you should remember that the arrangement should be "telescopic"—either that the

drawing-room can be compressed into a snug boudoir or opened out into a large ball-room.

Now let us go up the stairs, and in designing the stairs make the treads wide and the risers low. The old, easy staircases we find in old houses used to be 6 feet and 7 feet wide, whilst their risers were never higher than $4\frac{1}{2}$ inches or 5 inches. What a difference to the narrow ladder staircases we find nowadays.

On the first floor, in economical planning, the first thing to consider is the position of bath-room and water-closet. We must try and arrange the water-closet so that the soil-pipe shall enter the drain where the principal ground-floor water-closet does, so that the soil-pipe (and soil-pipes are expensive things) shall act as the ventilator. Therefore the water-closet must be, if not over, nearly over, the water-closet to ground-floor, and the best position for the bath-room is generally over the pantry. In any case it should be over some such office, so that in case of any overflow the water does not ruin some expensive tapestry or paper in a reception-room. If you put the bath-room over the pantry, you can take your waste-pipe to empty over the trap which takes the pantry sink. The bedrooms will be disposed over the rooms you have arranged on the ground-floor. When planning bedrooms, these things should be borne in mind. First, that you do not want so much light (otherwise windows) in a bedroom as you do in a sitting-room. One window to each bedroom will generally be sufficient. Secondly, always draw, when you plan the bedrooms, the position of the bed, placing it well out of any draught from window or fireplace and door. And, thirdly, always let your doors open so that when open they hide the room. I generally try to arrange that for a sitting-room the door will be in the wall at right angles to the fireplace and at the furthest corner from the fireplace, whilst in a bedroom the door will be in the wall at right angles to the fireplace but at the nearest corner.

The cistern-room should be over the bath-room, and it should be easily got at.

As to cupboards. Some housewives are crazed about them, and would like to have them sprinkled about the house as they sprinkle their bows and ribbons. But beyond a house-maid's closet near the water-closet, and a linen closet near the bath-room, so that the hot-water pipes or cistern can keep the linen aired, I do not see the necessity of putting many cupboards about. There are, of course, the cupboards in kitchen, scullery and store-room, but I think cupboards in bedrooms are unsightly things, and that wardrobes are much more useful. This is a matter, however, in which you will be guided by your client.

Well now, gentlemen, we have discussed the general arrangements of a house and the disposition of the different rooms. The individual tastes and idiosyncrasies of the client, and the exigencies of the site, will cause us sometimes, however, to alter in detail the positions of the rooms, but I think if we bear in mind the following points, where they will be possible, we shall not go far wrong in our plans:—

1. Have a good porch and hall, with the staircase not in full view of the entrance.
2. Have your pantry as near as possible to the entrance.
3. Have your dining-room and kitchen near your pantry and near each other.
4. If possible let all, or nearly all, your reception-rooms face the south; the kitchen and stairs and offices can then face the north.
5. Let your drawing-room be "telescopic" if possible.
6. Have your bath-room over your pantry.
7. Have as few passages as possible.

As to this last, which I would say is one of the most important, I would also add this. Never skimp the width of your passages. Three inches is worth three times as much in a passage as in a room. The three inches would not be felt in a room, whereas it would be very much felt in a passage; and I think the great problem in all house planning is to reduce as much as possible the necessity of passages, but where you have one, make it a wide one. No passage ought to be less than 3 feet 9 inches. Although we can copy (though not slavishly) the forms of the houses of the sixteenth, seventeenth and eighteenth century, their quaint gables, bay windows, oriels, turrets, porches, &c., we must adapt them to our modern ideas of plans. We can assimilate their good points and expurgate their bad.

Now let us consider the differences between designing a house for a client who likes these fine old houses, mullioned windows, oriels, &c., and designing a house for a client who wants sash windows and plain square rooms. In the one case you are not fettered; you can throw out a gable here, a gable there, and the more haphazard the design the more happy it seems to be. I have often felt that the backs and sides of some houses designed nowadays are more interesting than the fronts, and I think it is because the irregularity has not been studied. Studied irregularity is never pleasing. It is a fraud, and frauds are always seen through even if they cannot be explained.

Studied regularity, on the other hand, if there is nothing incongruous in it, is pleasing. We admire the tact, the skill and the thought that has been expended on it. But, for goodness' sake, do not let us go back to the times when, to conform to regularity, we have a staircase and landing with balusters showing through the middle of a window, so that the window-cill may be on the same level as the adjoining cills. If the cills must be on a level it is bad planning, and if they need not be on a level it is bad designing. As to the differences in plan between what I call the manor-house style and the eighteenth-century style, in a nutshell I would say, where in the one style you have irregularity in the disposition of the rooms, in the other you have regularity. In the one style you may put your bays out of the centre of the rooms and where they happen to come. In the other style you must think out before you decide on the general disposition of the rooms where you will have your bays and porticoes.

Mr. Briggs concluded by explaining several plans of houses he had built in various parts of Middlesex and other counties.

Mr. FRANCIS HOOPER proposed a vote of thanks to Mr. Briggs for his paper, coupling the name of Mr. Goldsmith for reading it. He thought it was advisable for an architect to show his client a garden plan. Local materials, he thought, ought, as far as possible, to be adopted, and the design to be harmonised with local architecture. The remarks as to the aspect of buildings he concurred with, though the remarks as to prevailing winds on the coasts were new to him. He thought great care should be used as to the position the fireplace should occupy in a room, as also the position of windows. The fireplace should be clear of the door and of draughts. Doors were also liable to be put in the wrong place.

Mr. BERNARD DICKSEE seconded the vote of thanks. He differed from Mr. Briggs as to the arrangement of the dining-room window.

Mr. BRODIE advocated the provision of ample cupboard-room, even one in which a portmanteau could be unpacked.

Mr. FLETCHER thought that few persons liked angle fireplaces except on paper.

Mr. BEALL and Mr. GOLDSMITH also made some remarks.

The PRESIDENT said Mr. Briggs, in his paper, seemed to have covered the whole ground of planning a house. He did not think, from an artistic point of view, that rooms should be too lofty. One feature he had noticed in some of Mr. Ernest George's houses was the arrangement of a chamber over a corner fireplace in a room 16 feet high, approached by an internal staircase, whence the lady of the house could see all who entered the room. Windows of bedrooms should face the rising sun. A room should never face due west. Architects should plan the furniture with the buildings, especially in regard of bedrooms. The vote of thanks as proposed, and further coupled with the names of Mr. Belcher, Mr. R. Blomfield, Mr. Ernest George and Mr. Newton, who had lent drawings, was passed by acclamation, and the meeting terminated.

CŒUR DE LION'S CHARTER TO NORWICH.*

ON May 5, 1894, we shall reach an interesting anniversary in the history of our city. On that day the citizens will have enjoyed 700 years of self-government, for on May 5, 1194, King Richard I., by the charter here displayed before us, granted the city to the citizens and their heirs, with the right of choosing their own governor from among themselves, subject to the king's approval. The actual "granting of the city to the citizens" is perhaps hardly brought out in the charter so definitely as might be expected, which no doubt accounts for the fact that this charter has sometimes not received the attention which it deserves, being, for instance, ignored by the compilers of this roll of the governors of the city. There can, however, be no doubt that the citizens were then for the first time made lords of the city. They paid the king 200 marks (133*l.* 6*s.* 8*d.*) for the privilege, which is thus recorded in the Royal Exchequer Roll of the following year:—"The citizens of Norwich have granted to the king 200 marks for having confirmation of the liberties of their city, and for holding the city in their own hand, so that they may answer for the due farm (or fixed rent) at the exchequer."

I have called King Richard's grant the first grant of self-government to the citizens for want of a better way of expressing what was given. But it is necessary to observe that, although this is a truth, it is very far from being the whole truth. The subject of the political condition of boroughs in early times and the exact character of the privileges they enjoyed, is a very obscure one, and I can claim no absolute certainty for the attempt I am about to make to explain the political condition of Norwich at the time of King Richard's charter and the benefit the citizens derived from it.

* A paper read at the annual meeting of the Norfolk and Norwich Archæological Society, by the Rev. W. Hudson.

It would take far too long to discuss all or many of the numerous matters touched upon in the charter. We may pass over those which concern the rights of the citizens as traders in other places. Our business is with the citizens at home, and (what we shall see was even more important) their relation to the king, who was their lord. I am anxious to keep this point clearly in view, that (apart from their commercial dealings with outsiders) the two great objects the citizens had to provide for were (1) to satisfy the demands of the king as their rightful lord, and (2) to manage their own internal affairs to the best advantage, so far as they were allowed to do so.

The same thing is true now, though under widely different conditions. The rulers of the city have to satisfy the requirements of the Imperial Government, as well as provide for the efficient administration of the city. The latter province of duty is tenfold more complex than it was in King Richard's day. As regards the former, the great difference is that in the days we are speaking of the Imperial power was centred in the person of the king, whereas now it is hard to say where it is. I could almost imagine that our mayors or town clerks would sometimes prefer to deal with a king who, though a trifle capricious, was yet always ready to give very substantial privileges in return for a handsome present, and who asked for money and very little else, instead of the miscellaneous host of heads of Government departments, who seem to spend their time in devising how many distracting orders they can send down to worry the brains and disturb the peace of local administrators.

Keeping this twofold aspect of municipal life and action in view, I will found my observations on three points of the charter. First, the grant of the city to the citizens; secondly, the title and office of the governor they were authorised to elect; and thirdly, the "husting" court, which they were allowed to hold once a week. If we can arrive at an understanding of these three points, we shall have a fairly clear conception of the municipal life of Norwich in 1194.

First, then, who were the citizens to whom the king granted the city? Our best help towards answering this question is to be obtained from the account given in the Domesday Survey of King William the Conqueror. In that survey Norwich is called a "villa" or town, and in it were 1,320 "burgesses." This was in the lifetime of King Edward the Confessor, say A.D. 1060. These 1,320 burgesses were not all circumstanced alike. They were under three separate jurisdictions or lordships. Fifty were under the lordship of the Bishop of Thetford, 32 under that of the Earl of East Anglia, and the rest, 1,238, under that of the king and the earl. The two former we have nothing to do with. The 1,238 were organised in what was called a "burgus," or borough. Of them the king and the earl had the "soc, sac and custom." The meaning of the two first words has been much disputed. In general terms they amount to this: that the burgesses had to seek their justice from a deputy of the king, and that all the money paid as fines for wrong-doing or as tolls or other like payments went to the king and the earl, the king taking two-thirds and the earl one-third. Then we are told, "This whole town rendered 20% to the king and 10% to the earl," besides some smaller dues. Now we have, I think, in these few details a very important clue to the political condition of the burgesses at this early date. Why does the survey so carefully specify the number of the burgesses, and to whose jurisdiction they belonged? Was it to ascertain the amount of the population? Certainly not. It was because each one of them held a tenement which was chargeable with a certain definite payment (in the nature of a rent) to the king if they were in the "burgus," to the earl or the bishop if under them as lords. The king's agent directly demanded this payment from the holders of these tenements. In this respect they were so many separate individual tenants of the king. On the other hand, when we are told that "whole town" paid a lump sum to the king and another to the earl, it is plain that this implies that they had the power of acting in a body. The king's agent did not collect that payment from them separately; they collected it amongst themselves and paid it to the agent through some accredited head of their own. Who that head was and what else they were allowed to do amongst themselves will come under the other two branches of our subject. At present I would point out that at the time of the Norman Conquest the burgesses were in some respects individually responsible to the king, in others they enjoyed a communal organisation as one body working and acting together.

The Conquest did not materially affect this condition. The Frenchmen who settled in Norwich were formed into a "new burgh," that is, they had their own separate and corporate relations to the king, as the older burgesses had. Soon after this, through the rebellion of Earl Ralph and the disgrace of Bishop Stigand, their jurisdiction fell into the king's hands. It appears also that in the course of two or three generations the distinction between the old and the new boroughs died out. There is mention of the two organisations in Stephen's reign, but (except possibly one doubtful

reminiscence) there is no trace of it afterwards. The "citizens," then, at the time of King Richard's charter, were, with a modification noted below, the burgesses mentioned in Domesday, with their individual obligations and communal organisations which we have there traced out.

We pass on to our second point, the right to elect a provost of their own—an important step towards becoming lords of their own city. What was a "provost"? I cannot help thinking that the word is an unfortunate one, and has led to a good deal of misconception. It was not the word used at the time, unless, perhaps, by the Frenchmen of the new burgh. The great mass of the citizens, speaking in their own English tongue, would call him their "reeve," or the "borough reeve." It was the Latin clerks who translated "reeve" into "prepositus," ruler, and the Norman-French turned "prepositus" into "provost." This is the history of the word. When we come to consider what kind of an office it described we are brought face to face with the much-disputed question of the origin of English boroughs. Some have thought that they were relics of the Roman occupation, a sort of political islands which survived the deluge of the Saxon invasion, and preserved, as in so many arks of refuge, the institutions of a bygone age. This theory has, I think, been quite discredited by scholars of the present day, even London (an undoubtedly Roman city) showing no trace of Roman institutions. Another theory, started by the courtly lawyers of the Tudors or the Stuarts, supposes that they were devices happily thought of by the early kings for the defence and well-being of their kingdoms. This is supported by no foundation of evidence. The latest theory is certainly the most reasonable. They were not relics of a former rule, nor an artificial invention of kings, but were the natural outcome of the increasing civilisation of Saxons and Angles, and more especially Danes. The influencing causes were not always the same. Most commonly, however, a town sprang up where some one or more commodities, such as fish or salt or iron, or foreign goods sought after by a settled population, could be procured and transmitted to those who needed them. If a powerful lord were there to protect the settlers so much the more was the town likely to develop. These two favouring causes are sufficient to account for the origin of Norwich.

Now, this being so, the townspeople being of the same race, habits and character as the country people, may we not reasonably expect to find them with similar institutions, only adapting those institutions to their differing circumstances? Our forefathers were much more clever than we are at making the same general principles give life to varying organisms. They did not, as we do, require every local organisation to measure itself by the same rule. What, then, was the condition of the country as these little commercial settlements (mere villages at first) grew up into important boroughs? It was divided up into a multitude of estates, which, long before the Norman Conquest, had assumed the form, if not the name, of a feudal manor—that is, each had a lord, who was as a little king in his own domain. Under him the greater portion of the land was held by tenants on condition of rendering certain services. Exactly a similar state of things is found in such a town as Norwich. The lord was the king and the tenants were the burgesses. The only difference was in the nature of the services. On the country estates the services were ploughing the lord's land, sowing his crops, reaping his harvest. In the town, where these services were not needed, the obligation was fulfilled by a money payment. Every burgess held what was called a "burgage" (that is, a piece of land with a house on it), for which he paid a rent called "landgable," or land rent. The 1,238 burgesses of Domesday were the persons who held these "burgage" tenements, and, as individuals, paid the "landgable" rent. When Richard gave the city to the citizens, and they became its lords, these rents passed into their hands. The list of the tenements was carefully preserved, and several such lists have survived from the time of Richard II. to that of James I. I am not sure that we should be right in concluding that the burgage tenants correspond exactly with the "citizens" to whom Richard granted the city. I think not. I think that even then, to become a "citizen," it must have been necessary to apply to the existing body of citizens for admission into their fellowship, and to fulfil the conditions of satisfying their inquiries as to character and credit, and also to pay an admission fee. Every organised society, such as even the burgesses of Domesday were, must exact some such guarantee from its members.

This concerned the separate obligation of each burgage holder to his superior lord, the king. But, as we have seen, they had already for many generations been banded together in some sort of corporate unity. For this purpose they must have had some head. Who was he? We may find an answer in the ordinary manorial organisation. In every ordinary manor the tenants elected one of their own number every year as a sort of foreman, who was called the "reeve," or, in Latin, "prepositus." The office was not looked upon as an honour. It was a burden which might not be refused. The duties con-

sisted chiefly in overlooking the tenants and labourers in their work, and (in general) being their responsible representative to the lord. He and four others also represented the township in the king's courts of justice. In a small manor the lord would deal with him directly, but in a large manor there was also another official, a bailiff. He differed from the reeve in this way. The reeve represented the tenants to the lord. The bailiff was the lord's agent, appointed by him, and representing his interests alone. In the time of Domesday, no doubt, the government of the "burgus" of Norwich was organised in this way. The burgesses in their corporate capacity would elect a "borough-reeve," who would be responsible for the lump sum which had to be collected, and would be their head in their internal self-management. The "lord's bailiff," through whom he dealt with the burgesses and their reeve, would at that time be the earl, at a later time either the constable of the castle, or, more generally, the sheriff of the county. But it will be observed that before King Richard's charter the borough-reeve was appointed by the king, not elected by the burgesses. Blomefield states that King Henry I. appointed the first provost in 1122, but there is no authority for this assertion. There is no reason why all the towns on the king's ancient demesne (as Norwich was) should not have had a reeve (as London had) from their first organisation as a "burgus." It is easy to see why the appointment fell into the hands of the king. Even in some country manors a powerful lord would claim the right to appoint the manorial reeve himself. The reeveship of a flourishing borough was too important an office to be left in the hands of the burgesses until the political necessities of the kings led them to seek their favour and pecuniary support by granting them this privilege.

The "provost," then, was the old "borough-reeve," who, although for obvious reasons of policy he had long been appointed by the king, was yet in his real character the chief citizen, the head and centre of their corporate unity. It was a great step which King Richard now enabled them to take. It amounted not only to placing in the hands of the citizens the choice of their own head, but to making that head for the future his bailiff or agent. Hitherto the reeve had been only half their own, and, moreover, between their representative and the king was the sheriff. Now their head was to be altogether of their own choice, and in the most crucial part of their obligations (the money payments) he was to deal directly with the king's chancellor at the exchequer in Westminster.

Our third point will bring us to what the citizens, no doubt, thought the most valuable part of the king's gift—the control of their own court of administration. "We have granted," says the charter, "that the husting may be held once only in the week." The "husting" was a local court. The word is of great interest, and, like "provost," has led to much misconception. The best known husting court is that of London, and Lord Coke and other great lawyers, who thought London had been the front and origin of all municipal life in England, maintained that Norwich and other places which had such a court derived their court from London. All the local evidence is against this theory. The court was not now established for the first time either in Norwich or elsewhere. This very same clause appears in a charter granted to London itself on April 23 of this same year. Yet the London court had been founded by King Canute nearly two hundred years before. It appears also in other contemporary charters, and especially in one to the citizens of Lincoln, with the significant difference, that instead of saying that the "husting" may be held once a week, it says that the "burward mote" may be so held. That is the "mote" or meeting of the burgesses. The "husting" then, was the old court of the burgesses, the "borough-mote," as it is sometimes called. We may pause for a moment over the significance of the word "husting." It is a Danish word, meaning "home-court." It is generally explained as describing a court or assembly held in a house instead of in the open air. Primitive assemblies were always held in the open air, and were so held in Norwich—most probably on Tomblond. Before the time of King Richard, however, another court or place of meeting had been established in the tolbooth in the Market. They may have both continued together for some time, as they did in London. Here, apparently, the opening court had at this time died out. All the business of the citizens was conducted in the tolbooth.

It has occurred to me, and very likely to other students (I know of one) that the reason why this court in a borough was called a "husting" was this: The name first occurs in London in the reign of Canute, the Danish king of England. Now, Canute had a body of soldiers called "hus-carls," that is, fighting men attached to his house or royal residence. May not the "husting" in London have been a special court attached to the "king's house" (not merely a court held in any house)? We may suppose that while for certain purposes the burgesses of London continued to assemble in the open air, Canute established in his "house" a court for dealing with such judicial matters as land disputes or inheritance. A similar

practice would, of course, be followed in Winchester, which was also a royal residence, and there the word "husting" was early in use. The practice would naturally be followed also in all the towns on the king's demesne, only, strictly speaking, the name "husting" would not be so appropriate. As a matter of fact, it never was used in Norwich by the people themselves. It was used by London clerks to describe a similar court to that which they knew by that name in London. The Norwich people called it their city (or borough) court. According to this theory, a "borough court" corresponded to the manorial court, the earliest name of which was "halimote" or hall-mote; that is, the "meeting held in the lord's hall," the court afterwards known as the "court baron."

In Norwich (though not a place of royal residence) there was, in Canute's time, one of the four great earls among whom he divided the kingdom—the Earl of East Anglia. To him we may well ascribe the establishment of such a court as the king's "husting," only, instead of summoning it in his hall, he held it in the "tolbooth," the official place where the king's toll was received. Here, also, in course of time the open-air meetings of the burgesses came to be held. It appears, then, that in King Richard's time the borough court included two separate functions. On one side of it was the old assembly of the burgesses, where they transacted the business of administering the city, admitting new members, regulating trade and perhaps dealing with debts and breaches of contract and other commercial matters. On the other side it was the king's court (not as king, but as lord of the city), in which were decided matters relating to land and inheritance. But although it was the court of the city, it could hardly be called the court of the citizens, for the president was appointed by the king, and the king took all the profits.

What King Richard's charter did was to give the control of this court, with all its profits, to the citizens. They for the future elected the provost, who presided over it. The fees, the fines, the tolls, passed into their hands. The laws and regulations they chose to lay down for the management of their internal affairs were no longer subject to the consent of their lord.

We may thus estimate to some extent what it was that the citizens of Norwich gained on May 5, 1194. It was not a municipal birth. They had been a "borough" for probably 200 years already. Nor was it a great municipal revolution or change of constitution. None such was made. What happened was this: Instead of feudal servants, or at best feudal tenants, they became freeholders of the city. It was as if the tenants on a large estate were told that, on payment of a fixed annual rent to the owner, they might have the estate and manage it for themselves and keep the profits. It was, indeed, only a beginning of self-government which they entered on. Their power did not extend over criminal jurisdiction. Perhaps if a thief was caught in the act they might take him and even hang him. But the right to punish all the petty offences which now come before our police magistrates was not granted till thirty years later, and numerous other privileges, administrative, judicial or commercial, were added from time to time.

In short, King Richard's charter placed the citizens of Norwich in the position of a young man just entering on the control of a large and promising piece of property. How they and their successors conducted themselves in their responsible position, what successes and failures they met with, what difficulties they had to face, and what changes they passed through, all these things have been told by Blomefield and others. Many details of how they did their work still remain to be worked out from the records which they left, and which have survived from within 100 years of this charter. It is a matter of congratulation that these valuable records will, before many weeks are over, be transferred from their present unsatisfactory receptacle to the safe and commodious muniment-room provided for them in the Castle Museum.

Looking back upon the 700 years which have elapsed since the granting of independence to the citizens, we may see that through most of that time Norwich has stood amongst the very foremost of English towns. If of late many others have rivalled and outstripped it, that is owing to natural causes which cannot be controlled. The city still ranks high, and while we wish that its prosperity may continue, we may in connection with our present subject express a special hope that it may never want wise and patriotic rulers, whose only aim shall be to administer its affairs for the increase of its welfare and for the common good of all its inhabitants.

A Meeting of the Badenoch district committee was held in Kingussie to consider offers for the erection of a new iron bridge on the Spey at Kingussie, to replace the existing timber structure. It was decided to build it at the site of the present bridge, and the committee accepted the lowest offer, which was that of Messrs. Sommerville & Co., Dalmeir Bridge Works, near Glasgow, the sum being about 3,264*l*.

EVOLUTION IN ART.

THE paper read by Mr. Henry Balfour before the Applied Art Section of the Society of Arts on "Evolution in Decorative Art" appeared in *The Architect* on April 13. Sir George Birdwood, K.C.I.E., C.S.I., presided at the meeting, and in opening the discussion said that Mr. Balfour had favoured the Applied Art Section of the Society of Arts with a paper of high scientific quality, to which they had listened with the deepest interest, and for which he had earned their most grateful thanks. It was difficult to offer any criticisms on it, for Mr. Balfour had treated his subject in so severely inductive a manner that one had to accept his conclusions, from the facts so carefully established by him, as self-evident principles. Moreover, while the traditional types of decorative art were yet in their mechanical stage, and were merely so many dead forms, and before the quickening spirit of art had breathed life and beauty into them, and they had thus become truly decorative, they excited no artistic sympathy in him, even though they might already have become symbolical. In his opinion, indeed, Mr. Balfour's most instructive paper belonged not so much to art as to ethnography, and for this reason the observations he ventured to offer would rather be round-about than on the admirable paper they had been privileged to hear that evening. The paper really dealt with changes in decorative types rather than with evolution in decorative art. The fact is that in art there is no such thing as evolution, but more or less isolated and veritable "creations"—for their law cannot by searching be found out—by men whose genius is a true divinity. These men found schools and styles, and after them begins a regular course of devolution, at every step worse devolved. This is really as true of "decorative" as of "fine" art; while the facts of devolution are even more strikingly and pertinently illustrated in historical than in unhistorical (*i.e.* "primitive" and "savage") decorative art. Thus Sir John Evans has shown (*Numismatic Chronicle*, xii. 127) the type of the laureated head on the gold stater of Philip of Macedon, in its passage through southern, central, western and northern Belgium, Gaul and across the Channel into Britain, passing through successive devolutions under the hands of its savage, or rather barbarous imitators, until it becomes in one series an ear of wheat, and in another a quatrefoil. Of course there may be change without devolution of type, and change with evolution, as when the Greeks took the symbolical palm-head of the Assyrian "Tree of Life," which owes all its interest to its symbolism, and transfigured it, unfortunately, with the loss of its symbolism, into both the "palmette" and the "honeysuckle," two decorative types of perfect beauty, and, indeed, rather created after an ideal archetype than evolved from a material prototype. For illustrations of changes in well-known types of historical decorative art he referred to the chapter on "The Knop and Flower Pattern" in his "Industrial Arts of India," and to Count Goblet d'Alviella's "Migrations des Symboles," which latter treated of the permutations of every known symbolical decorative type in at once the most learned and scientific manner. The Polynesian types dealt with by Mr. Balfour he (the Chairman) thought might be instances of evolution from devolved types, originally Indian, transmitted through Southern Asia. There was first ignorant and unskilful imitation with gross devolution of type, and from that point there was a limited degree of evolution, for the human mind, even in its lowest developments, insists on coherency and symmetry, so far as it can command them. If we will search out the absolutely aboriginal sources of decorative types we must go back to the utmost backward of the world's history, beyond the genesis of the human race, of even the animal kingdom, and trace them to the ultimate molecules of the external elements of infinite nature. There is no intermediate point of origin either in the "evolution" of decorative types or of the æsthetic sense they gratify. The æsthetic sense is, in short, inherent in nature and latent throughout nature, and he (the Chairman) would not limit the point at which it became nascent and conscious. In form, we can trace in nature everywhere a tendency to the evolution, through successive gradations, of ever more and more perfected beauty. For an instance, take the peacock's plumage—wherein we can trace, through successive steps, the gradual evolution of its decorative type, from its first remote suggestion, in a vague spot of blue on the tips of the bronzed green feathers of the body of the bird, to its final complex elaboration of form and colouring in the characteristic "eye" of the feathers of the tail; and the pea-fowl's sense of their beauty is proved not simply by the peacock's proverbial pride, but by the fact that peacocks are now all distinguished by "eyed" plumage, simply because the peahens have always preferred handsome to plain mates, and refused the latter all opportunity of multiplying their plainness. Similarly, peahens are now all dingy-hued because the more brilliantly-coloured ones were so run after by the peacocks that they were all sterilised, and long ago became extinct. This law of sexual selection reigns with rare exceptions throughout the animal kingdom below men and monkeys, and sufficiently

demonstrates the presence of the æsthetic sense throughout it. Then, passing to colour, we find in vegetation its fundamental colour to be green, but by some law that is the property of plants they all in the higher orders tend to express themselves in ever nobler developments of colour, and first, after green, in yellow, and then, through orange, in red, and through purple in blue, the noblest of all colours. Of course the unit of a flowering plant is the leaf, a tree being nothing more than a colony of individual leaves, and the successive modifications of the leaf into the calyx, corolla, stamens, pistils and ovules, or after fertilisation seeds of a flower, is simply to provide the embryo leaf, which is the heart of heart of the seed, with sufficient protection and provision against the winter and other risks to insure the propagation of the plant in the spring. These modifications imply higher and higher efforts of generative force, manifesting themselves naturally in higher and higher developments of colour as well as of form. But still it is impossible not to feel that every flower rejoices in its own beauty, and that its joy is essentially of the same kind as our own—at least, in so far as it is an elementary mood and aspect of it. Note the phenomena of the fertilisation of a flower. It is quite a fashionable wedding "feast of nectared sweets, where no crude surfeit reigns," the colours of the corolla representing the gay dresses of the bride and bridesmaids, the fluttering butterflies the banners, and the humming of the bees the marriage bells. In its anatomy and physiology, and one might almost say in its scenic arrangements and social economy, it is all one with a human marriage, and it is hard to believe, in the face of such suggestions of a universal *anima mundi*, that the predominant sentiment of the two functions is not identical, and that plants do not participate in the artistic sense common to all animals, and are not in some degree conscious of their own ministry to the beauty and nobility of the life of this world. There always seems to me more than a latent æstheticism even in gems and other crystalline and coloured stones, their very beauty being, as it were, expressive of the ceaselessly operative tendency, which might almost be called the insuppressible desire, of the whole material "creation" to realise its highest spiritual ideals.

CARPET DESIGNING.

(Concluded from last week.)

IT is, I suppose, conceded on all hands that, while there yet remains much to be done, there has been a very great measure of improvement in the design and notably in the colouring of carpets within the last twenty years. And what has been done has been almost entirely the work of manufacturers and of the designers in their employment, who have been trained and guided by them. And here let me say that the manufacturer is not marked off by any hard-and-fast line from the designer. Occasionally the two are united in one person, and it frequently happens that the manufacturer is his own colourist. If he have any natural gift for colour, which I suppose will be admitted as possible even by those who look upon him as a mere master-mechanic, it can scarcely fail to be aroused and cultivated by the atmosphere of colour in which he lives and moves. In many cases without putting pencil or brush to paper he can, and does, impart to a design all that it has of distinctive merit.

Designers and writers on design steadily ignore the fact that in a carpet form is only a secondary matter as compared with colour. This is partly because graceful forms can only be approximately expressed, and in coarse fabrics can merely be suggested, and partly because in actual use the drawing is always seen distorted by foreshortening and broken up by furniture.

To illustrate the point that colour is more important than design, I may say that not unfrequently an effect of colour is decided upon before there is any thought of a design to carry it, simply by picking up tufts of coloured yarn, as one might gather flowers, and arranging them into combinations, subject to a certain dominant scheme. When this is done, a design is drawn with the sole object of displaying these effects. In fact, design is only a scaffolding for the construction of the real edifice. I am disposed to say that in many cases form is of no more importance in a carpet than is sunset.

It is pretty obvious that writers on decorative art ignore colour because they are not themselves colourists. As I have elsewhere said, it might almost seem as if they lived in a monochromatic world, so insensible do they seem to be to the existence of colour. Now for this they are not wholly to blame, and so long as they have the modesty to recognise their own limitations, one must not be too hard upon them. The fault lies in the entire want of any provision for the systematic teaching of colour as a branch of ornament, of equal and, in some cases, of greater importance than what is commonly called design.

It seems to be thought that while drawing and composition must be carefully and systematically taught, colour may be left to take care of itself; that the colourist is born, not made; and

that, therefore, there is no use in trying to train him. The student, as he grows up, finds that, judging by the examples set before him, form is all important; and when, by-and-by, he develops into a decorative artist, or an art critic, it is not to be wondered at that colour occupies a very secondary place in his thoughts.

In my opinion, colour requires to be taught with even greater care than design, and for this reason, that the colour sense develops later than the feeling for form. There are good reasons, we are told, for believing that this is true of the race as well as of individuals, and that the Greeks of Homer's time had no true sense of colour, but only of light and shadow. Be this as it may, it is a matter of common observation that the power of drawing is usually acquired long before there is any indication of a mastery over colour. In the case of painters who have been great colourists, their early work shows no indication of any such gift.

At South Kensington there has until lately been little indication that the training of the public or of art students in colour has been present to the minds of those responsible for the collection and exhibition of that vast mass of material. The recent arrangement of the tapestries in a large well-lighted hall is a step in the right direction, but the bulk of the valuable collection of textiles is still in a dark gallery, where it is very difficult to see them. There is in the adjoining Natural History Museum a collection of minerals, many of which are so exquisite in colour that they seem to have been collected and exhibited as much for their beauty as for their scientific value. Whatever may have been the motive, there is little to compare with them for suggestiveness in the Art Museum. There colour appears, so to speak, incidentally. If an object selected for its form or its rarity has also fine colour, well and good, but there is little indication that anything has been selected for its colour alone. But the thanks of all who are interested in art applied to textiles are due to Professor Middleton for what he has done, and has been so undeservedly attacked for doing. I hope he will persevere in the course he has adopted. In the museum of a country where weaving is one of the great industries, textiles should have a more prominent place than they have hitherto occupied.

This leads me to ask, Why should we not have a colour school and a colour museum? When one thinks of what such a collection might be if selected and arranged with this sole end in view, the prospect, to anyone with a keen colour sense, may almost be called intoxicating. It need not be costly on the whole. Why should not some of the lovely effects now produced in various materials be made the basis of such a collection? One continually sees in shop windows, in all sorts of fabrics, passages of colour that would be well worth preserving. Fashion may at any time decree a return to magenta and emerald green, and the formation of such a collection as I advocate could not fail to have an effect in averting such a consummation, if fine pieces of colour, instead of being a memory of the past, were to be kept permanently before our eyes. Such a collection could not fail to have an effect, not only upon decorative art, but upon the rising school of painters. It need not be confined to manufactured articles only. Beautiful bits of natural colour, when these are capable of being preserved, might be added, such as the minerals I have referred to, with birds, insects, shells, lichens, and so on.

It may be said that all these can be found by those who have eyes to see them, but one does not follow this principle in other branches of education. If such objects were brought together and arranged with descriptive labels analysing the scheme of colour in each case, and showing by means of an example placed alongside how such a scheme might be applied, either to a picture or to a piece of decorative art, the educational value would be enormous. It is probably for the want of some such training that in the revival of the feeling for good colour, which is so marked a feature of the last twenty years, a greater number of artists have not turned to carpets. For in colour possibilities, carpets of certain makes stand at the head of all textiles. There is no other woven fabric in which the number of colours is unlimited in theory and so large in practice. It is wonderful that the scope thus given does not prove a greater attraction to those artists who are naturally stronger in colour than in design. It might be thought that in looking round for a medium in which to express themselves they would have eagerly seized upon carpets.

Such a scheme as I suggest might, if carried out, be not without influence on other arts—music, for instance, in a way not at first sight apparent. We know that Richard Wagner was unable to give form to some of his great tone-conceptions until he had arrayed his person in gorgeous colours. And so a sensitive composer straying into such a chromatic paradise as I have conceived might receive inspiration which could bring forth a great symphony. And the converse holds good, for in one's own experience music is sometimes found very stimulating and suggestive of decorative conceptions. A successful design has been originated on the back of a concert programme. But lest I may be crediting music with more than its due share of

such influence, it is only fair to say that a long, dull sermon has been known to produce a similar result.

I have said that great advances have been made in the colouring of carpets. The improvement has been mainly along two lines. First, tints more beautiful in themselves, and more suitable for their purpose, have been used, and secondly, elaborate gradation has been adopted where flat tints were once used. At one time, in making reproductions of Eastern carpets, their variety of tint was looked upon as a defect. But it has long since been recognised that perfect evenness of colour is not desirable. A great advance has been made by using gradation of colour in flat designs. In my opinion one of the reasons why many people prefer representations of raised ornament in a carpet is because of the delicate gradation of tints which is necessary to express it. I am surprised that this has not been pointed out by writers on decorative art, and that no credit has been given to those who have solved the problem of retaining all the charm of gradation and of combining this with perfect flatness of treatment, avoiding on the one hand any imitation of relief, and, on the other, the bald uninteresting effect of flat ungraduated colour.

Here let me say a word in my own defence against a possible charge of inconsistency. I have elsewhere held up French designers as worthy of imitation in their methods of representing light and shade in carpet designs; but in recommending young designers to study these methods if they wished to produce designs of a similar type, I was merely pointing out the shortest way to practical commercial success. I carefully guarded myself against expressing any approval of such designs, and made it sufficiently clear that, personally, I heartily disliked and condemned them. I imagine that the chief difference between myself and my critics lies in this, that I know there is and is likely to be for some time to come a considerable demand for such designs, and I am not prepared to advise young designers to neglect them. Their doing so would not lessen the demand, which would be supplied somehow, and the only result would be that they would find it more difficult to earn their bread and butter. The improvement in taste which—in England, at all events—we may hope to see brought about, must be effected by other means, such, for instance, as those I am now endeavouring to suggest. But the foreign and colonial trade will remain, and in some of these markets we cannot expect to see a high standard of design adopted for a long time to come, if ever. Will it be argued that English designers are entirely to neglect the only methods which will enable them successfully to cater for such markets? I am not prepared to say so.

Mr. Lewis Day confessed to a little disappointment at not having heard anything about carpet designing, which he wanted to learn about; he had only heard the "bitter cry of the manufacturer." Mr. Millar's complaints touched him personally, first as a designer; secondly, as having dabbled more or less in criticism; and thirdly, as having been one of the wicked judges at South Kensington; and he might, therefore, say a word on the other side. He did not quite agree with the author that the designer resented the conditions under which he had to design. If he was really a designer, he thought those conditions rather stimulated him. The reason why designers did not take to carpet designing was partly that it was more difficult, and required more knowledge of technique than some other things; and partly, perhaps, because so much depended on colour, and he understood that the manufacturer had that in his own hands. If the manufacturer were a colourist he might make beautiful things out of designs which were insufficient, but he might also spoil a good design, and an artist did not greatly crave to work in a medium over the final stage of which he had no control. No doubt the good manufacturer came in for some of the abuse which the bad one deserved, and he shifted the blame on to the retailer. Mr. Millar said the dealer "gauged the public taste," but in that he could not agree. He forced his own taste on to the market, and the public could only buy what the dealer provided; many beautiful things were stillborn simply because the dealer did not like them. The dealer or salesman managed to sell what he liked, and what he did not like he declared would not sell. The pattern-book was a great source of complaint to the wall-paper manufacturer, instead of an advantage, because the best things showed to great advantage in a pattern-book, and the consequence was that the worst things were bought, and, when used, were condemned. Some years ago, in criticising English art generally, he alluded slightly to carpets, and expressed the opinion that the good designs then current were mainly, if not entirely, borrowed from the East, and he was inclined to think so still, notwithstanding the very beautiful things shown to-night. The best carpets on the walls were emphatically those which were most distinctly Eastern. He might make, perhaps, one exception, that taken from a Coptic tapestry, which showed greater originality than any of the others. He did not quite know who Mr. Millar was girding at, for he did not know of any class of artists who advanced precisely the opinions attacked by the reader of the paper. He did not think any one contended that

people should always be struggling for something absolutely new, or that they should not be influenced by what had gone before. Such a thing was impossible; a man often did what he thought original, and then found it was very like something he had seen before, just as a well-turned phrase which came to him as an inspiration often turned out to be a quotation. At the same time, when a thing was too obviously traceable to its source, that was rather against it. He did not know that any one had sneered at the attempt to introduce Persian forms; designers of carpets could not do better than start with a study of the Persian, but it did not follow that they should go no farther. Nor did he think any one nowadays insisted on showing the repeat in a pattern. He had himself insisted on designers basing their pattern on a geometrical construction, but it did not follow that that construction should be obtrusive to the eye. Mr. Morris had said no doubt that it was pleasant to see a frank recognition of the lines on which a thing was designed, but that was only an individual opinion. When a manufacturer bought a design and did not produce it, it was not always the fault of the artist. He had known cases where such designs were left for years, until that particular kind of thing began to be known, and then, when it was too late, they were brought out. There was great want of pluck on the part of manufacturers. It was suggested that a school of design should be established on the plan of Mrs. Dunlop Hopkins. It would be time, he thought, for the Americans to come and teach us how to design when they had done something themselves better than we were doing already. That was not yet the case. We had a teaching institution at South Kensington. It was not his business to defend that much-maligned school, but if it was not doing what it was established to do, it would be better that it should be stirred up to do it than that a rival school should be set up. With regard to piracy, the Americans were not the only pirates. He had said that he had not designed carpets, but he had seen his wall-papers reproduced in carpets, very much to his annoyance. If the British manufacturer were in earnest in desiring honesty in trade, he would insist on having a copyright law which would protect designs of every kind. He had enjoyed the paper very much, and hoped that in criticising it he had not exceeded the limits which the author prescribed for himself.

Mr. Arthur Silver writes to the Society:—Although I can thoroughly sympathise with Mr. Millar and lament with him for the apparent scanty encouragement which is offered to the most important of our textile industries, yet, looking at the matter from a designer's point of view, I am inclined to consider that one reason is owing to the fact that designing for carpets presents more obstacles than designing for other fabrics. In the first place, he must master the technical difficulties, and possess a sufficient knowledge of working on the ruled paper. Assuming that the difficulties have been overcome, and he has accustomed himself to the work at a very considerable expenditure of time, he will find that his experience, bought at the expense of ignoring other work, is available for carpets only; whilst experience gained in designing for one printed fabric qualifies for innumerable other fabrics. Another obstacle is owing to the numerous varieties of cloths. Many manufacturers have their own special gauges, and though the character of the design may suit one manufacturer, he may not employ the gauge upon which the design is worked; this involves a serious risk to the designer. To be an expert with the ruled paper is an exclusive business, and so keen is the competition that many manufacturers who insist on adhering to a "trade" custom of buying designs by the yard would be aghast with an outsider who required the equivalent of remuneration according to the time involved. Therefore, taking into consideration the obstacles to be surmounted, the tedium of the mechanical process, the keenness of competition and the time involved in obtaining a knowledge of the various makes, and of the firms who employ them, I am bound to state that designing for carpets presents a maximum of risk for a minimum of profit, even though the "outsider" may present designs which some manufacturers will acknowledge to be entitled to payment considerably in advance of the market rates. If, therefore, the outsider who has more or less experience in the branch finds the means of livelihood barely forthcoming, I cannot see how those who occupy the greatest prominence in decorative design can reconcile themselves to the making of experiments to produce a practical drawing when other work, which under the circumstances would involve more interest to them, must remain in abeyance. I must not omit to state that some manufacturers welcome small-scale freehand drawings, which have afterwards to be translated to the ruled paper; this certainly overcomes some objections, but the method cannot be successfully indulged in until some experience on the ruled paper is first obtained, otherwise their work is liable to be non-practical. But designs in this form are only welcomed by a very few; some cannot mentally realise the actual result, and others object to the double outlay involved in transferring it to the ruled paper. Mr. Millar refers kindly to my work; it is only fair to state that such merit as it is entitled to is mainly due to his exceptional

powers of lucid exposition of the technical points. As one keenly interested in this matter, I am grateful to the Society of Arts for having brought this subject forward, and to Mr. Millar for dealing with it. Before concluding, I should like to emphasise the extreme value of the suggestion made respecting a school or museum of colour for industrial work. I trust this will be further agitated. I may mention that during the course of a year I have applications from many hundreds of students and "designers"; about 1 per cent. will exhibit a skill in design beyond the average, but not one in 500 can show an original, harmonious and practical colour scheme. This should speak for itself.

GENERAL.

The Society of Engineers meet at the Town Hall, Westminster, on Monday, May 7, when a paper on "A Deep Boring near Freistadt, Austria, by the Canadian System," will be read by Mr. R. Nelson Boyd.

The Governors of Dulwich College have arranged to open the Dulwich Picture Gallery on Sunday afternoons, from two o'clock to five, during the months of May, June and July.

An Exhibition containing over a hundred crayon portraits by John Russell, R.A., besides examples of amateurs' work, was opened on Wednesday in the Imperial Institute.

The Choir of Norwich Cathedral was reopened on Wednesday, the works of restoration undertaken by Dean Lefroy having been completed.

The late Miss Harrison, of Wakefield, has left 500*l.* for beautifying Wakefield Cathedral.

The Death is announced of Mr. David Payne, a Derbyshire landscape artist. He was the son of the late Mr. John Payne, contractor and mason, Annan. Educated at Annan parish school, he was a classmate of Mr. William E. Lockhart, R.S.A. His father apprenticed him with an Annan house-painter, and after serving his time he gave up house-painting in favour of more refined tastes. Removing to Derbyshire some twenty-five years ago, he devoted his life to painting the scenery there.

Wick House, Richmond Hill, originally built by Sir Joshua Reynolds for himself, and from which he painted his picture of the view of the Thames Valley looking over Petersham Woods, was put up to auction on Tuesday, but withdrawn at 5,000*l.*, which was the only bid.

Mr. Waterhouse, as honorary treasurer, was able to announce at the dinner of the Artists' Benevolent Institution, on Saturday, that the contributions received during the evening amounted to 1,700*l.*

The Liverpool Corporation have agreed to carry out alterations and additions to the Central Fire Station and Police Buildings, Hatton Garden, at a cost of 26,000*l.*

It was announced at the meeting of University College, Liverpool, that Mr. Henry Tate had presented to the college a list of standard works valued at about 5,500*l.* It was also announced that Lord Derby, who had succeeded his brother as president of the college, had given a donation of 10,000*l.* to endow a Chair of Anatomy.

Stables have been completed for the Glasgow Corporation in view of their taking over the tramway system on July 1. So far, nearly two thousand horses have been purchased, chiefly from Ireland.

Mr. George Simpson has been appointed burgh assessor, town architect, and practical adviser to the Leith Corporation, in connection with the Leith improvement scheme.

The Royal College of Music, South Kensington, erected from the designs of Sir A. Blomfield, A.R.A., was opened on Wednesday by the Prince of Wales.

A sum of 2,000*l.* will be required for the purpose of acquiring freehold land on which to building a vicarage as a memorial to the Rev. F. J. Ponsonby, late vicar of St. Mary Magdalene, Munster Square, and already the sum of 1,200*l.* has been collected. Mr. Andrew Oliver, of Bedford Row, has given 3,000*l.* towards the building, and operations will begin immediately.

A Committee of the Cheshire County Council have considered the question of establishing an agricultural college for Cheshire. The committee reported that the establishment of an agricultural school, with an experimental farm attached, would be of great benefit to the county, and they suggested that Messrs. Thomas Rigby and John Edwards, with Mr. R. P. Ward, the organising secretary, should obtain information with regard to suitable sites for such an institution. The report and recommendations were adopted. It was estimated that the cost would be about 11,000*l.*

The Subscriptions to the testimonial which is to be presented to the efficient secretary of the Surveyors' Institution, Mr. J. Rodgers, are being promptly contributed, and, as the list will be closed at the time appointed, any members who have not paid should not allow the opportunity to escape.

The Architect.

THE WEEK.

In the North of [England there was an agreement among architects about the abilities of FREDERICK RICHARD WILSON, of Alnwick, who died on Monday last. As an archæologist and a writer he was considered to be equal to any of his contemporaries. His knowledge of architecture was admitted, and wonder was often expressed that he was satisfied with the limited sphere for the exercise of so much talent which was afforded by Alnwick and its neighbourhood. A period of forty years had elapsed since he came there to take charge of the important works which the Duke of NORTHUMBERLAND had commanded in Alnwick Castle. Afterwards he was sent to Rome to study Renaissance work as a preparation for designing the interior decorations. In that way Mr. WILSON became closely associated as a friend and adviser with the PERCY family, and the relations between them continued to the end of his life. Before his settling in Alnwick Mr. WILSON had been engaged under Sir CHARLES BARRY and Mr. SALVIN. He was the author of several essays on archæological subjects, and his book on "The Churches of Lindisfarne," to which his leisure hours during several years were consecrated, is of great value. Mr. WILSON's energy was not confined to professional pursuits. He took a large share of the responsibilities of public life, and gained respect by his efficiency and zeal. At the time of his death he was in his sixty-sixth year.

CHARLES JACQUES, who died in Paris on Monday in his eighty-first year, was an artist who was never sufficiently appreciated by his countrymen. He was an associate of MILLET, and we believe it was mainly owing to his example that the pupil of DELAROCHE abandoned costume pictures in order to represent peasant life. JACQUES had not the pessimistic bias of MILLET. He did not consider that field work was an infliction, so he made pictures and drawings in which the peasants appeared as men and women who went through their work vigorously, as if they enjoyed it. As a draughtsman he was far superior to MILLET. The latter did not care much for action; most of his figures are standing still, or not engaged in any work which is tiring. JACQUES, on the contrary, was happiest when representing men who were reaping or threshing, and his mastery of light and shade enabled him to make the simplest scene interesting. While MILLET was supposed to be a revealer, a poet, a philosopher, JACQUES was by the majority of amateurs regarded as a sort of reporter, and his fidelity to life was valued as if it were only a commonplace quality.

THE citizens of Bristol, in common with the rest of the Western people, have gained a peculiar sort of reputation for their adherence to a belief in the advantages of slowness and sureness. It will not cause much surprise to learn that they waited until last week before erecting a tablet to record the connection of JOHN CABOT and SEBASTIAN CABOT with Bristol. JOHN CABOT was a Venetian, and as a pilot he was engaged in Bristol. From time to time he made voyages to the Western continent. His son, SEBASTIAN, with two other brothers, accompanied him. At one time it was supposed that SEBASTIAN was born in Venice, but it is now generally believed that he was a native of Bristol, and the new tablet announces that fact for the benefit of posterity. He was more than an adventurous sailor, for he was able to prepare charts, a difficult task at that time, and the penurious HENRY VII. paid him twenty shillings for a map of Gascony and Guienne. The king did not give an appointment to SEBASTIAN, who accordingly appeared to consider himself as a citizen of the world. When WOLSEY wished to organise an expedition, CABOT could not accept the leadership without the consent of CHARLES V., as he was in the emperor's service. According to the inscription on the tablet, he "sailed in the ship *Matthew*, A.D. 1497, and discovered the continent of America." That he was the first man of that time to reach some part of so large a continent is likely, but he was only one among several navigators who could claim a like dis-

inction. The tablet has been provided by the Clifton Antiquarian Club, but the people of Bristol would do well to pay for a statue of the brave man, who, as the first governor of the Merchant Adventurers, may be said to have initiated English commerce.

A MEETING of the West Riding County Council was held on Wednesday at Wakefield. The subject of the new county offices was again brought forward. It will be remembered that in March the general purposes committee recommended that the tender of Messrs. ARMITAGE & HODGSON, amounting to 72,506*l.* for the erection of offices in Wakefield, should be accepted. An amendment was, however, carried that the subject should be sent back for further consideration, with a view to the erection of the offices in Leeds. On Wednesday it was proposed that the decision to provide offices for the County Council, its committees and officers at Wakefield be adhered to. There was a long discussion, and various amendments were proposed. One was, "That the tender of Messrs. ARMITAGE & HODGSON, contractors, Camp Road, Leeds, amounting to 76,824*l.*, be accepted for the works set out in the general specification, comprising a council chamber or hall, and offices for the administrative and other work or business of the County Council." It was rejected, fifty votes being against it and twenty-three in favour of it. Finally, the original motion was carried.

THE Art Union of London was founded in 1837, and it was then considered to be especially an experiment for the promotion of art. Afterwards similar institutions were established in the provinces, in Ireland and in Scotland. The objects of subscribers were not entirely disinterested, for they had the expectation of winning a painting and the certainty of obtaining a print, but on the whole they may be credited with the intention of co-operating for the advantage of art. On that account, when the Act was passed for the exemption of literary, scientific and artistic societies from local taxation the Art Union of London could easily have obtained the advantage of it if proper application had been made. The opportunity was neglected until the present year. On Monday the Art Union appealed against the assessment of the offices in the Strand by the overseers, on the ground that the premises were only used for the promotion of art. A society that has a dual purpose always is in a difficulty in maintaining that one is paramount. While the counsel for the Art Union relied on the commissions which are given out of the funds, the counsel for the overseers of the district represented the Union as a lottery that was upheld for the advantage of the subscribers. The judges of the Queen's Bench took the latter view, and the appeal was dismissed. What is more important, the Art Union was declared to be an unauthorised art lottery. It is therefore open to any one to take advantage of that judgment, and it will be prudent for the Council of the Art Union to adopt such a course as may prevent, too, the waste of the funds on useless litigation.

ONE effect of the Parish Councils Act has been already exemplified in Stourbridge. Six years ago the Boundary Commissioners recommended that the poor law union of the district should be divided, as at present it comprises parts of two counties. Several of the guardians considered the operation ought not to be delayed any longer. One member opposed the recommendation on the ground that if unions must be always conterminous with county boundaries, it would be necessary to erect two hundred additional workhouses. As the cost of one is at least 25,000*l.*, for the sake of the building trade it is to be hoped the Boundary Commissioners will be able to insist on the realisation of their ideal arrangement. Another objection offered for deferring the dissection of the Stourbridge Union was that between old age pensions and parish councils workhouses would not be so necessary as they have been in times when there were fewer Acts of Parliament. A majority took that view, and Stourbridge may be long before it has a second workhouse. It does not matter, of course, that the existing building has been condemned, and that from its position poor people are compelled to make toilsome journeys before they can obtain relief.

PAINTING AT THE ROYAL ACADEMY.

WHEN the President of the Academy finds it necessary to give a sort of testimonial to this year's collection of paintings, and generously appeals on behalf of the young contributors, people will naturally assume that the works are insufficient to recommend themselves, and require the aid of a favourite advocate. It needs no hypercritical eyes to discern that in every one of the galleries there are representations of commonplace subjects for which compensation is not found in the manner of treatment. While so much may be admitted, the artists have a right to ask whether the average character of their works is not at least creditable to their tact as men of business? Excellent paintings have of late years failed to attract purchasers in Burlington House, and after wandering around the provinces have come back disconsolately to their creators, although they are not sure of a welcome. Is it prudent to persevere in the production of pictures that will be admired in London and country towns as if they were only elements in a spectacle, but for which nobody will give an adequate price? It is easy for right reverend divines, like his lordship of Peterborough, to descend upon the artist's task as if it consisted simply in the endeavour to express ideas; but supposing the expression is like an unknown tongue to his contemporaries? When the Bishop affirms that "Living art must always strive to enlarge the boundaries of expression, to bring new forms of knowledge, thought and feeling within its compass; it must always be struggling to catch something that has been uncaught before, to cast over each new aspect of nature or character which science has revealed or life has developed that transparent veil of beauty without which they remain alien from our sympathies," everybody who is compelled to take the world as it is must realise that his lordship is one of those patrons of art who consider it is undignified to display their esteem by drawing cheques. The ordinary buyer of pictures, like the Bishop, believes that the artist "needs to be sustained in audacity," but the test he applies is the coming down from the empyrean to his own level. The audacity which paints highwaymen, five-o'clock teas, imitations of plates of fashions, broken-down gamblers, dogs and horses whose thoughts are to be guessed, the quarrels of inane lovers and other storms in teacups, is sure of receiving another kind of sustenance than episcopal sympathy, and one that landlords, butchers, bakers and tax-collectors prefer to all other varieties. It is only necessary to look at the print-shops to discover the kind of art which is bought for enjoyment. As long as the market rules prevail, it is absurd to expect that painters will close their eyes to facts and paint what is unsaleable in order to gratify the whims of theorists, and "to soothe, to enlighten and to strengthen" worthy gentlemen like the Bishop of PETERBOROUGH, who will only "sustain" artists by an approval expressed in the finest words the dictionary affords. Although it is not of this world, even ecclesiastical audacity cannot sustain itself on conditions so immaterial.

An exhibition in which one-fifth of the contents of the principal rooms are portraits has, of course, an element which may occasionally be attractive but does not exalt. When from the sameness of subject or treatment a visitor is doubtful whether he has not seen some of the pictures at a former time, the collection in general appears to be less valuable. It must also be allowed that pictures which suit the present condition of the market are like other saleable commodities, and can only be considered in bulk; it is the abundance of the supply which is the chief source of interest. But in all the rooms, we might say in all the strata on the walls, pictures are to be found which merit preservation because they are happily inspired or reveal signs of exceptional power. Let us suppose that a representative of a municipality was authorised to expend money out of the public funds on a few works, of which the interest would not be transitory, need he return empty-handed and report that the season was unfruitful?

Following the catalogue order, he would find in gallery No. 1 *The Last of the "Florentia,"* 1588, by Mr. WATSON NICOL, an interesting example of one of those incidents which if imaginary are credible, and cast a sidelight on history. The Highlanders are raising from the shore to the top of the cliff a treasure-chest which, from its apparent

weight, contained gold that was to be used for the subjugation of England. The subject is novel and affords an opportunity to show tartaned figures in action, and the scene of the incident being on the Scottish coast, there is an opportunity for introducing both rocks and sea. Sir F. LEIGHTON'S *Fatidica* is one of three paintings of a decorative class, which are valuable as suggesting how much effectiveness can be insured by a few colours. *Tea*, by Mr. G. D. LESLIE, shows a girl in a mob cap, and the treatment of the face is very like the President's manner, but the features are English. Mr. W. LANGLEY has been hitherto known as a water-colour painter, but there is nothing of the novice about *Never Morning Wore to Evening but Some Heart did Break*. It might have been painted in rivalry with the picture which made a reputation for Mr. F. BRAMLEY. In both an old woman is comforting one that is young, and it may be supposed that the grief is caused by a shipwreck. But while the scene in one is within a room in the early morning, in the later picture the pair are seated near a quay wall in full daylight. There is not much difference in the execution, but Mr. BRAMLEY'S arrangement allows of more display of skill in light and shade. Mr. HOOK'S pictures are always welcome, and for his *Seed Time* he has travelled a little inwards. *Bolton Abbey*, by Mr. J. W. NORTH, shows also a departure for fresh fields and pastures new, since we see a place where trees are green and not brown. Another discovery is seen in Mr. BISCOMBE GARDNER'S *Devil's Punch Bowl*, for that spot in Haslemere appears as impressive as any chasm in Arran.

The President's *Summer Slumber*—a blooming girl in a pink dress, with long hair, lying near a window—is the principal work in the second gallery. As censors are unable to find fault with the figure, they have gratified themselves in pointing out the discomfort of the ledge on which she rests, but on that account the picture gains *vraisemblance*, for it can be supposed sleep came suddenly. The *St. Sebastian*, by Mr. S. GOETZE, suggests the human affection of which the Prætorian captain was the object. In the picture we see IRENE and another Roman lady adopting the simple but loving surgery which saved the martyr for a time. GUIDO, unlike the majority of old masters, suggested that only one arrow was used; Mr. GOETZE represents no more than a pair. His figures are admirable in modelling and colour. Mr. HOOK'S *Practising without a Diploma*—a girl extracting a thorn from a child's finger—is as pleasing as any of his later works. *Feeding the Pigeons in Piazza San Marco, Venice*, is a trite subject, but Mr. LOGSDAIL has suggested how well strangers can still find pleasure in the old custom.

The third gallery causes more disappointment than the others this year. Mr. HACKER, in common with the latest Associates, hardly does justice to himself in his *Temptation of Sir Percival*. The knight is without much refinement, and a frown does not impart beauty to his countenance. The painter may have, however, wished to suggest that Sir PERCIVAL, whom ARTHUR and his knighthood called the "Pure," was the sort of man who was destined to prefer the cowl to the helmet. Mr. POYNTER has of late years shared the common fate of artists who teach, for his works are more correct than genial. The young people in *Hours Serene* are proportioned according to rule, but they take their pleasure as sadly as if they were engaged in the opening dance in a modern ball-room. The colour is academic, but unluckily an *Entrance of Cleopatra in Tarsus*, by Mr. H. H. GILCHRIST—which might have been painted in Pesth—has been hung immediately over it, and by contrast Mr. POYNTER'S work appears to be only one of the productions of the Science and Art Department, with a sort of official absence of vitality. Mr. ORCHARDSON'S *James Dewar, Esq., F.R.S.*, is the better of his two portraits, and it is fortunate it is to be preserved in a building like Peterhouse College. It is not a flattering likeness, and it never could be taken for an enlargement of a photograph. What we find expressed is the impatience of the student of science, who would have students advance at electric speed in order that they might reach the shore like NEWTON, and have at least a glimpse of what law accomplishes in nature. Mr. H. MOORE is among those who have abandoned their old resorts, for in *Lowestoft Boats Running in a Breeze* he paints a sea which is less blue than

usual, and therefore 'comes' nearer to the experience of ordinary seagoers. Mr. C. W. FURZE, in his *Robert Bridges, Esq.*, has a portrait that will bear comparison with Mr. ORCHARDSON'S. The *blasé* look of the student of literature is as true as the eagerness of the student of natural philosophy. The *Orpheus*, by Mr. SWAN, seems to be the incomplete realisation of an inspiring idea, but it is doubtful whether it would have gained a place on the line if sent in a couple of years ago. The artist has not had much experience in preparing for exhibitions—that is creditable to him, and allowance must be made if he is not quite at ease in what is for him a novel position. Mr. FILDES'S *H.R.H. the Princess of Wales* is a portrait which would gain approval in any European or American exhibition. The absence of accessories seems more becoming the dignity of the subject than if they had been introduced in the conventional manner.

The Lady of Shalott is one of those unpaintable subjects which are always tempting painters. In the legend there is a vagueness which gains acceptance for it, but when the curse comes to be realised with the aid of paints, we cannot help seeing it resembles a good many of the narratives which could only pass among people who had never outgrown their childhood. Mr. WATERHOUSE is at least as successful as his predecessors, but nobody but a Japanese is competent to attempt such a subject. Few artists are as happily constituted as Mr. ALMA-TADEMA, for he never fails through an inadequate subject, and although a stranger, English weather does not appear to affect his temper, colours or pencils. *At the Close of a Joyful Day* represents a Greek girl gazing from the top of a flight of steps on the sea, and they are fortunate who will be always able to gaze on her serene beauty. Mr. WATTS has an impressive Eastern figure, a sort of JOB, as the subject of *For He had Great Possessions*. The handling is as vigorous as would be needed in a fresco of the old school.

The Summer Afternoon in the Atlantic, by Mr. SOMERSCALES, which is found in the fourth gallery, represents the Battle of Ushant in 1794. The Greeks believed that "on earth there is nothing great but man," and it is at least true in combats. In naval engagements a painter can do little more than suggest a contest between two vessels, and he cannot expect to arouse as much interest as would arise from a picture of a fight between a couple of school-boys. The proof of this fact is found wherever large numbers of pictures of sea-fights are found. The Greenwich gallery is one instance, but still more convincing is the Amsterdam gallery, for although the ablest painters were employed, the rooms containing the pictures are found dreary by the Dutch as well as strangers. Mr. PRINSEP'S reverence for womankind disqualifies him to paint such a picture as *A Versailles*. The *ménades*, or as CAMILLE DESMOULINS described them, the JUDITHS, who marched from Paris carrying young and old with them irresistibly, might be engaged in singing one of the tuneful choruses which characterise the GILBERT and SULLIVAN operas. The French painters should be acquainted with the facts, and they make the women furies; but in England we are too domesticated, too happy to be able to realise revolutionary fury. *The Close of a Stormy Day: Vale of Clwyd*, is by Mr. JOHN FINNIE, a landscapist whose reputation stands high in the North, and this picture by itself would sustain his position. Mr. DOLLMAN'S *Gold* is an experiment. Practice with a different class of subjects does not disqualify the artist to suggest the universal passion to which all things can be sacrificed. The men and women who follow and seek to impoverish the miser before he reaches the tomb are ably contrasted; there are no figures to let in the picture, and the introduction of the half-starved dog that alone appears to be honest increases the effect. The picture deserved a place on "the line." *The Ordeal*, by Mr. BOUGHTON, shows a passionless sort of woman walking through the snow reading a prayer-book, while some faggot-cutters and a jester in the background retail calumnies about her. We must confess we prefer the artist's Dutch and Puritan girls. If the foremost figure were omitted the rest of the picture might serve as a design for a Christmas card.

It is not often a gallery in the Academy contains two opposite neighbours of the character of Mr. HERKOMER'S *All Beautiful in Naked Purity* and Mr. DRAPER'S *Sea Maiden*. The former is another instance of the artist's

versatility, for it is summerly in its brightness and clearness. The girl being alone among the trees and as unconscious of shame as EVE before she received a name, the figure is a realisation of innocence rather than a representation of a mortal being. The woman who lies in the drag-net is intended to be "strange haired, with sad singing lips," but the amazement excited among the fishermen by her appearance imparts a quality to the picture which is not ideal. Mr. H. G. RIVIERE, in *The Argonauts and the Sirens*, selects the moment when the voice and lyre of ORPHEUS overwhelmed the songs of the temptresses, and there is more satisfaction in looking at his picture than at those where the men appear to be doomed.

The First Christmas Dawn, by Mr. A. GOODWIN, in the sixth gallery, was apparently inspired by the line, "Then opened Heaven's chancel while the shepherds gazed in fear." If mystics and divines as well as poets have believed in celestial architecture which was adapted for earthly uses—a city, a new Jerusalem that was to come down prepared as a bride adorned for her husband—a painter is allowed to suggest that at the beginning of our era one of the buildings was to be seen dimly by the shepherds abiding in the field. Mr. GOODWIN has done his work with due restraint. The whole picture is overspread with a fine blue, the glory that shone around, and the architectural vision is indicated with delicate and broken white lines. The scene at Bethlehem is shown below, and of course on a small scale. The painting is a daring effort, which many people will not be able to appreciate, for some will expect more definiteness, while others will object to the introduction of anything that appears made with hands in the heavens. But as the style adopted is Gothic, which of all others is most associated with religion, there is no more irreverence in supposing a correspondence between heavenly and earthly architecture than between their music. If peace on earth was announced on the first Christmas dawn, there are pictures enough in the room to show how far the promise is from realisation in the nineteenth century. By some accident or intention, the battle-pieces are placed in this gallery. Mr. S. L. WOOD represents *Horse Artillery Going in Under Fire* in a realistic way. Mr. T. DAVIDSON is no less unflinching in his *Trafalgar*, which depicts the critical moment when NELSON was removed to the cockpit. Mr. S. BERKELEY illustrates the French assumption of a *Sunken Road at Ohain*, the "pitiless chasm" which was supposed to have been one of the causes of the defeat at Waterloo. According to VICTOR HUGO, "Riders and horses rolled in together, pell mell, mangling each other." Anyone acquainted with the district is aware that the chasm was about a foot and a half deep, and yeomanly recruits would not come to grief in encountering it, but to HUGO's vision all things were on a colossal scale, and Waterloo was not a battle between ordinary mortals. It was Heaven's endeavour to overthrow the greatest of the TITANS. The little fence which would barely serve to keep lambs from straying accordingly was transformed into a pitiless chasm. It is a pity Mr. BERKELEY'S talents were not occupied with a less fanciful subject, but it must be allowed he seems to have been inspired by HUGO'S spirit. *The Black Watch at Bay, Quatre Bras*, has been painted by Mr. W. B. WOLLEN in a convincing style. A similar scene was depicted recently by an Edinburgh artist, and the painting was popular, in which officers and men displayed their coolness by being as indifferent as if on parade. At Quatre Bras men were furious. The practised hand of Mr. CATON WOODVILLE has produced the best battle-piece of the year in *Badajoz*, 1812. He represents the scene on the morning after the final attack, when the Iron Duke, or rather Viscount, was overcome by the signs of destruction. Grim visaged war there reveals itself, but something still worse could then be witnessed within the town. It will be said that sieges and battles are preferable to the terrible exercise of power over weakness which Mr. J. S. SARGENT has derived from ancient examples for his *Lunette and Portion of Ceiling* for the Boston Library. Decoration can rarely be judged piecemeal, and without some indication of the general scheme, the part exhibited can only be described as a strongly coloured adaptation of Egyptian and other figures.

The seventh room contains Mr. STANHOPE FORBES'S

Quarry Team, a strongly painted group of horses dragging stone over rough ground. Higher skill is seen in Mr. CHARLTON'S *After the Battle: Sedan*, where the riderless horses are shown in a mad gallop across the battle-field. Mr. SEYMOUR LUCAS has returned to the Elizabethan period, and has found another subject in the preparation to meet the Armada. *The Call to Arms* is an illustration of MACAULAY'S ballad, and represents the Sheriff calling on the people of a town like Dartmouth for volunteers. As usual, every figure and every costume are carefully prepared.

In the eighth room, the *Child Enthroned*, by Mr. T. C. GOTCH, resembles a May Queen that was before exhibited. The child has a girl's face, but being seated in an uncomfortable chair, wearing a sort of cope, and having a nimbus, we assume the child is no mortal being. The dress is a credit to the artist's painstaking toil. *Psyche before the Throne of Venus*, by Mrs. H. RAE, corresponds with Mr. MORRIS'S Chaucerian version of the scene, and therefore the figures are only of a mortal type.

Among the remaining paintings there are not many works which our imaginary agent would covet, but in at least eight of the galleries he would find examples that would be creditable acquisitions for any public gallery, and therefore worthy of forming part of any private collection.

SOCIETY OF ARCHITECTS.

AT the meeting of this Society a paper on "The Influence of Freemasonry on Architecture" was read on Tuesday night by Mr. D. F. Ranking, Mr. George Highton, president, occupying the chair.

Mr. Ranking said:—I hardly know whether the title which I have given to the few words you have kindly allowed me to present to you this evening may not be somewhat misleading. When one speaks of the influence of Freemasonry on architecture, the mind not unnaturally turns to Freemasonry as it exists to-day, with its vast organisation both social and charitable, its multifarious degrees and ceremonies, its lists of titled members, and its claims of descent in unbroken line from the builders of Solomon's Temple, if not from the builders of the Tower of Babel. But my intention is not to touch on the somewhat mythical, and certainly quite unsupported claims of the present Freemasons to represent a school or college of architects, who are said to have carried the science throughout Europe, if not through the world. We may, I think, dismiss any theory of such supposed origin, whether Roman, Collegium, Culdees, Benedictines, or what not, as purely fanciful. I would propose rather to speak of the mysticism to a portion of which, at least, the masonic bodies are the heirs, and ask you to consider whether the idea of embodying in actual lasting form the doctrines taught by this mystic philosophy may not, in some measure, account for the sudden rise and development of what is usually known as Gothic architecture.

It never seems to have been satisfactorily settled why the type of ecclesiastical architecture should have undergone a change in the twelfth and thirteenth centuries; to what this change owed its origin; or why it should show its most strongly-marked features in one part of Europe while in other parts it failed to establish itself or ever become naturalised. There has been a general tendency to trace the change in general form back to Eastern sources, but no good reason has been given for supposing that it came from thence, save the idea that the Crusaders may have brought back with them the forms of Saracenic architecture.

Payne Knight, in his "Principles of Taste," ascribes the origin to the corruption by Saracens and Moors of the Classical architecture of Greece and Rome. Kerrich, in the "Archæologia," derives the shape of the arch from the "vesica piscis," and he was not, perhaps, very wide of the mark. Governor Pownall, in the "Archæologia," considers it to be the imitation in stone of timber construction. Stukeley, in the "Itinerary and Archæologia," states that Pointed architecture was originally brought from Arabia, where it was derived from the imitation of groves of trees.

The spread of the new style has been credited to bodies of travelling freemasons, working under the direction of monks, and carrying certain traditional rules and secrets from country to country. Pownall says that the Collegium, or Corporation of Freemasons, first formed Gothic architecture into a regular and scientific framework by applying the models and proportions of timberwork to stone. They are said to have been formed into a corporation by the Pope, and to have been first established in England about the early part of Henry III. It has been objected to this that the Church would not have called in a body to aid in building Christian churches which, if it existed at all, was of Gnostic or Manichæan origin.

It is also said that the resemblance between the specimens of the style in different parts is not sufficiently close to justify the idea of a common origin or a united brotherhood engaged in building; the Scottish Gothic differs from the English, the French differs from the German, and both from the Flemish. As for Italy, which should have been the centre of ecclesiastical architecture, Gothic architecture never appeared but as a foreign importation, generally the work of German architects, and never established its ground far beyond German influence. Dean Milman says, "Rome is the city in which Gothic architecture has never found a place, and in the rest of Italy it has never been more than a half-naturalised stranger."

The cradle of Gothic architecture was the north-east corner of France; thence it spread over North France to the Loire, through the country of the Langue d'Oïl, and on to the Langue d'Oc; it also spread northward to England and Scotland, and east to Germany.

In France, St. Denis was built in 1135, and was followed by the cathedrals of Rheims, Chartres, Bourges, Amiens, Notre Dame at Paris, and St. Ouen at Rouen.

In England, between 1150-90, rose Kirkstall, Fountains, Darlington, Llanton, the entrance to the chapter-house of St. Mary's at York, portions of the Abbey Church of Selby, the choir of Canterbury, and the chapter-house of Lincoln, between 1186-1200. The transepts of York were raised between 1215-56. The west front of Peterborough between 1200-22, and Salisbury between 1220-58.

Scotland was affected as to the spread of the new architecture by its distance from the rest of the world, and by constant internal troubles, but Kelso was built in 1128. Kirkwall, begun in 1138, was not finished till 1540. St. Andrews was built between 1163-78.

In Germany the church of St. Elizabeth, at Marburg, dates from 1235.

This great outburst of magnificent church architecture during two centuries might seem to point to a wave of pious enthusiasm passing over Europe, and manifesting itself in the erection of buildings symbolising in their main arrangements and ornaments the great truths of Christian doctrine. My own belief is that, on the contrary, this new architecture was in its character essentially anti-Christian, as Christianity was taught by the Church. That it was indeed entirely symbolical, but that the symbolism was of a strongly Gnostic and Manichæan character, and entirely opposed to the doctrine expressed by the altar within the churches. I believe that the whole symbolism is pantheistic in a sense, and intended to teach, in opposition to the orthodox Trinitarian theology, the doctrine of the existence of a dual creative power; of one central, ineffable deity, from whom proceeded numberless lower intelligences, and of a central, correlative power of evil, existing of necessity because of the existence of good, and therefore coeval with good. The chief symbols used to express these doctrines would be the cross, the plan of a double cube, the circle, the rose, the equilateral triangle, the pentagon, the hexagon or double equilateral triangle, and the vesica piscis.

I am well aware that to all these figures a Christian symbolism is given; but my contention is that such is not the true and original symbolism, nor is it the sense in which they were intended to be read by those who first introduced them into European architecture.

At the time when Gothic architecture took its rise, two strong anti-Christian influences were beginning to make themselves felt in Europe. The Crusades had brought numbers of the knights into contact with Oriental philosophy, and with the remnants of the neo-platonic schools of Alexandria. At the same time the mystic doctrines of the Jewish Kabala were first being publicly set forth after being, according to the Rabbis, handed down as a secret knowledge for centuries. These systems acted and reacted on one another, and borrowed from each other doctrines and symbols. Thence was evolved a system of philosophy, partly compounded of Gnosticism and Manichæism, partly of Kabalistic tradition. This philosophy dealt largely in symbols and veiled, in fact, the whole of its teaching in symbolic figures. The main points of its teaching were the existence of a central all-embracing deity, who, being infinite, could not himself create, since creation implied limitation. From this deity, called by the Kabalists the Ain Soph, proceeded two creative deities, male and female in nature, and from these again proceeded others, making in all ten, known as the Sephiroth. These together formed the creative intelligences by whom the worlds were created. Since all forces in nature are equal and opposite, the existence of good necessitates the existence of evil; therefore evil was not rebellion against good, but an equal antagonistic power, absolutely necessary for equilibrium. Everything in nature owed its origin to the creative power of the active and passive principles, the male and female Sephiroth. The active principle was symbolised by fire, a perpendicular line or an equilateral triangle, placed on its base; the female principle by water, a horizontal line or an equilateral triangle, placed on its apex. The cross, one of the most ancient known symbols,

to them represented creation, the union of the active and passive principles of nature. This same sign, when taking the form of the Tau cross, and combined with the vesica piscis, gave the shape of the sacred Egyptian "Anch," the emblem of creative divinity. The union of the two equilateral triangles had a double meaning; when used of divinity it represented the struggle between the good and the evil principles of nature. It might also be read as of humanity, signifying the perfect archetypal man. Man was with this system neither a material unity nor a trinity of body, soul and spirit, but a being of a sevenfold nature, compounded of three divine principles and three earthly principles, kept separate by self. When the self was overcome and the lower principles were united with the higher, the perfect man resulted.

Man was also represented under the form of the microcosm, or pentalfa, the five-pointed star, which represented man with his five senses, and when placed within the circle represented the dominion of man over the universe, of mind over matter. The rose was one of the most sacred symbols, if not the most sacred; it represented in one light the Ain Soph, the eternal and unchangeable supreme; in another view it represented, like the vesica piscis, the female power in nature. The greatest mystery of all, that of sacrifice, was symbolised by the union of the rose and the cross. The Sephiroth, or creative intelligences, were arranged in three rows, called pillars; three, Wisdom, Love, Firmness, forming the left pillar, called the Pillar of Mercy; the three, Intelligence, Justice and Splendour form the right pillar, called that of Judgment; while the three, Crown, Beauty and Foundation, formed the middle pillar of Mildness. The tenth Sephira, Malkuth or kingdom, the world of phantoms, surrounds all in the shape of the vesica piscis.

In the early days of Christianity the shape of the building for ecclesiastical ceremonies did not matter. The whole doctrine centred in the altar; there was the only lesson to be taught, and it was the main and only thought of the worshippers. Therefore no change in the form of the building which contained the altar was necessary; development there might be, and additional magnificence, but the building itself was intended to teach nothing, since the only lesson was that of the altar. But when the West came in contact with the East, and the doctrines of the Church became mingled with the mysticism of neo-Platonists and Kabalists, the whole current of thought was changed among those who were imbued with the new ideas. The altar still maintained its chief position, but not as the sole object of veneration and source of teaching, but as one; perhaps the last link in a chain of symbolic teaching of an esoteric character, understood only by the initiated. That it might occupy its proper place in this scheme it was necessary that the building in which it stood should also symbolically show the chief points of this doctrine, which were, as we have seen:—

1. The Ain Soph, or supreme power, represented either as all embracing and quiescent by the circle alone, or the circle with the iod as its central point, or as giving forth as emanations the creative Sephiroth, when the rose became his symbol.
2. The Logos, or first emanation, from which proceeded the male and the female Sephiroth, wisdom and intelligence. These three together formed an equilateral triangle.
3. The union of fire and water, or the active and passive creative principles, symbolised by the cross, also by the interlaced triangles.
4. The existence of an active antagonistic principle to the first triad, shown by the reversed equilateral triangle. This was also symbolised by the black and white banner of the Templars, and by the grotesque devils used in ornament, most plainly in the devils of Notre Dame at Paris, which are reproductions of the Goat of Mendes, which the Templars were accused of worshipping under the name of Baphomet.
5. The supremacy of man in the material universe, shown by the pentalfa, and especially by the pentalfa in the circle.
6. The existence of man as the product of the contest of good and evil, and the possibility of perfection by the overcoming of self, shown by the interlaced triangles again, especially when placed in the circle.
7. The female creative power, the central point of Gnosticism, represented by the rose, which bore in this sense the same meaning as the lotus of the Indian and Egyptian mythologies, and by the vesica piscis, shown by the pointed arch, which also represented the tenth Sephira, Malkuth, the kingdom, the world of phantoms.

Now, who would be likely to take in hand the spread of these new doctrines? I think there is no doubt that there was but one body in Europe sufficiently learned, sufficiently daring and sufficiently powerful to do this. It was the Knights Templars. The symbolism, if so, should be found worked out in its completeness in the Templar churches. They were always accused of being tainted with Gnosticism, Manichæism and Judaism; and, so far as we can judge now, the accusations were well founded. My own belief is that the builders of the time learned the symbolism, but very likely not its meaning,

while engaged in construction under the orders and directions of the Templars, and that only in the buildings carried on under such conditions will the symbolism be found at all complete. When not working under such conditions the builders would make use of the forms they had been taught, but would combine and vary them as they were led by individual fancy, being guided by no fixed laws. With the fall of the Templars all guidance would cease and variation would be unchecked.

The doctrines remained as secrets with the Templars and Rosicrucians; and personally I look on modern freemasonry as representing the union of these esoteric bodies with the political secret societies of the Lollard type; and later, but not till the seventeenth century, with the craft guilds. The circular portions of the Templar churches I look on as undoubtedly Gnostic and Kabalistic in symbolism, as also the rose windows, such as those of Chartres, Westminster, York, Lincoln, Chichester and Lichfield.

No doubt these crude ideas of mine will seem to you, as practical men, highly fanciful, but failing better explanation of the reason for the rise of a new style of architecture, I submit it to your notice as a possible, if not probable, explanation.

At the conclusion of the paper Mr. E. J. Hamilton, vice-president, proposed, Mr. Walter Davies seconded and Messrs. Geo. Holland, Henry Lovegrove and H. G. Quartermain supported the vote of thanks, which was carried with acclamation.

EDINBURGH ARCHITECTURAL ASSOCIATION.

A MEETING of the Association was held on the 2nd inst., when Mr. Blanc, A.R.S.A., read a paper on the "Ecclesiastical Architecture of Scotland in the Fourteenth and Fifteenth Centuries." In studying Scottish architecture, he explained, he had been led to disagree with many writers on Scottish ecclesiology, and his object was to endeavour to trace to what extent Scottish church architecture in the period under review might be considered national. In the twelfth and thirteenth centuries church architecture, in England and Scotland both, had advanced on the same lines; but at the end of the thirteenth century friendly communication between the countries had been interrupted, and Scotland and England practically became separate countries as regards arts and literature. During the next hundred years, while England had passed into a new period, little or no progress was made in Scotland in church building, and when at the beginning of the fifteenth century Scotland began rebuilding, she had lost hold of her traditions of art, and was compelled to go back on the remains of the edifices in her midst for suggestion. England was then in the full flood of her third period, but in Scottish work none of the styles current in England were much expressed. Only in one or two cases was found the influence of the English Perpendicular, and the same was true of the French Flamboyant. Generally speaking there were to be found several features that might be said to be Scottish which had no prototype elsewhere, but were simply evolutions from existing material, and the chief influence was in the English decorative work. The lecture was illustrated with limelight illustrations, and one of the points which Mr. Blanc insisted on in his explanation of these was that Roslin Chapel was due to home influence.

TESSERÆ.

Egyptian Architecture.

THE Egyptians, of all nations, seem to have built and planned with the most exclusive regard to permanence. They designed to make antiquities. A dim bewildered instinct, a yearning after immortality, was the *primum mobile* of all their undertakings. They preferred an unconscious existence, in the form of hideous mummies, to utter dissolution; they feared that the bodiless spirit might lose its personal identity; and expected, or wished, after the expiration of the great cycle, to find all that they had left exactly as they left it—the same bodies, the same buildings, the same obelisks pointing at the same stars. Strange faith—that the soul, after all varieties of untried being, would return to animate a mummy. The Greeks built for beauty, the Romans for magnificence, the Orientals for barbaric splendour (the Chinese, indeed, for fantastic finery), the Gothic nations for the sublimity of religious effect or martial strength; a Dutchman builds to please himself; a sensible Englishman for convenience; others of that nation to show their wealth or their taste. But the Egyptian built in defiance of time, or rather propitiated that ruthless power, by erecting him altars whereon to inscribe his victories over all beside.

Imitation and Creation.

Novelty and beauty excite admiration, and naturally produce imitation; but this will be only for a time, for we should not be human beings if we finally did not endeavour to strike out a new path for ourselves; and then it is that we

shall bring to bear our knowledge, not for the purposes of imitation, but progress. With all just deference to the studies of our predecessors, with all our admiration for the styles of the past, our present object should be to consolidate and arrange the information we now have. From the lessons thus gained, the examples thus given, let us strike out a new path for the powers of the architect, and bring back the art to its normal state, which is one of gradual but sure progress, founded on scientific and artistic knowledge. We should perceive that merit exists more or less in all styles, and is irrespective of fashion, which is mutable and often unjust; that the principles of our art are fixed and certain; that however much long-received rules may be altered as circumstances may require, they are not to be despised or disregarded without careful consideration; that true construction is the vital principle of real progress; and that, besides the excellent and numerous examples of ornament we already possess, nature has still varied and inexhaustible resources in store for our study; and above all, that for the appliance of these means at our disposal, an earnest study, a just appreciation, a practical knowledge of all art are indispensably necessary, and can only be obtained by an industrious use of the hand and of the eye, as well as of the mind.

Romanesque Church, Granson.

The church of Granson is situated on the bank of the Lake of Neuchâtel, and is an instance of the use of the materials of some Roman building. The plan is cruciform, with aisles and a central tower. The nave has very small round arches, quite plain, carried on tall round pillars, which are evidently Roman work and are of different lengths, the bases being stilted more or less to accommodate them, and to make them range at the top to receive the arches. The capitals are well sculptured, with bold foliage deeply cut; the greater part are evidently Roman, but some are carved with figures of different kinds. One has the two horses rampant, back to back, and held together—an allegorical design very common in the South of France

NAVE, GRANSON.

in work of the eleventh and twelfth centuries. The vaults are barrel-shaped, carried on arches. The aisles have arches recessed in the walls, carried on pilaster shafts, the capitals of which may be early, but the bases are late, with deep hollows and corner ornaments. The aisle-vaults are a segment of a circle. The central tower is carried on four round arches, on massive square piers, with moulded imposts. The central vault is octagonal and domical, with a round opening in the centre. The upper part of the tower is of the thirteenth century. The first bay of the choir is early work, with a pointed barrel vault, the eastern bay of the thirteenth century, and very like English rude country work. The transepts have the western walls belonging to the old work and the eastern side, of the thirteenth century. The old work is probably of the eleventh.

Plurality of Styles.

The great prototype of architecture, nature, has many styles of beauty and employs them all. The horizontal, arcuated and vertical, or pointed styles, all find precedent in her domain; and though it could be proved that the Gothic was beyond all comparison superior to any other style in capability of the grander qualities, yet it would be opposed to all natural teaching to claim for it the sole and universal empire. Architectural practice should not only not be confined to one style—it should not be confined to any number; for beauty resides not in style, but in a vital principle that existed anterior to all styles, and to which all true styles owe their origin. A building might be so designed as to betray no trace of any style now existing, or that ever existed in the world, and yet be true architecture. It belongs to the very idea of a fine art, as distinguished from the mechanical ones, to yield a boundless scope to the inventive faculties throughout. There is an architectural beauty that will charm the sight and operate upon the mind like ceaseless music, that arises solely from the symmetry of proportion and form, and owes nothing to the trappings of decorative style. Erections which are never included in the category of artworks, such as some of our great chimneys, from geometrical beauty of plan, elegance of contour and a soaring height, often display higher qualities, reaching not unfrequently to sublimity, than the majority of church steeples or other buttressed or columnar erections can lay claim to. But the Greeks, the Romans, the Goths and others, we are still told, had but one style. It cannot be denied. But what have we to do with that, except to be thankful that it is not our case, and that we have many? Perhaps, too, they (the Greeks and the others) would have been glad to see our day of many styles. Perhaps in our plurality of style lies our best chance of going beyond them. A plurality of styles should certainly let us more into the central spirit of architecture than any one style could do. The best Gothic architect and the best Classic architect is the man who has studied both styles; who has examined the peculiarities and mastered the principles of all styles. He will best understand the great central art of architecture, which is neither Greek nor Gothic exclusively, but both, and much more, and the universal adoption of any one style to the abandonment of all others would not be progression, but retrogression.

Milizia's Writings on Architecture.

In architecture Milizia is remarkable for the boldness of his original speculations. He seems to have been a man of a powerful understanding, not very patient of labour; confident in himself, not taking up opinions on the faith of another, and never hesitating to expose and to defend his own. Architecture exactly wanted such a writer. It was in a languid state in Italy, vibrating like politics and religion between a slavish adherence to rules not understood and entire license. He who had liberated himself from these arbitrary shackles considered himself free from all restraint, and never thought of being reasonable, either in his submission or rebellion. Milizia applies reason to everything, and his fault is in being too reasonable; that is, in endeavouring to found upon reason certain practices which are only conventional, and which we follow because experience has shown that they please, without our being able to assign the cause of this pleasure. He writes with spirit, and frequently with a severe sarcastic wit, which will insure his being read; and he possesses a singularly happy and forcible mode of expression, to which the Italian language in his hands seems wonderfully suited. Had he written in one of our northern languages, he would have been frequently forced and harsh, and it would be difficult to translate him and preserve any portion of his spirit without falling into this defect. Though strongly vindicating his own freedom, he is much inclined to lay down arbitrary rules for others, and even to applaud a despotic exertion of the authority of government in matters of taste, not considering that the true use of rules is to guide, not to govern us; that they are merely the direction posts which mark the road pursued by some of those who have advanced farthest towards the conception of perfect beauty. Other and even better roads may possibly exist, but it does not show good sense to be ignorant of what has been proved good, or to desert the known track without well understanding what it is and what direction it takes, as well as the nature of the country we have to pass over.

Piling of London and Waterloo Bridges.

In Old London Bridge the original piling was never disturbed; the true bearing of the piles, though they existed only at the outsides of the foundations, was sufficient, and the starlings, sheet piling and filling in were only adjuncts to the strength, and were necessary only on account of the extra weight in width, and the structures upon the bridge which were added from time to time. These piles when drawn were as sound as when put down, and though upwards of six hundred years old they were convincing proof of the permanence of pile foundations when thoroughly embedded in the earth. Waterloo and London Bridges, which were both built by John Rennie,

have the same kind of foundations. The entire area of the bases of the piers is piled with elm piles, about 20 feet long and about 3 feet apart, and which penetrate the London clay, in the case of Waterloo Bridge probably to a depth of 18 feet, and in London Bridge about 18 feet 9 inches or 19 feet. On the heads of these piles were laid sleepers, and the loose earth between their heads was replaced with rubble concrete, on which blocks of Bramley Fall stone and brickwork filled up the spaces between the pile heads, immediately below the platform of oak planking which carried the first course of granite masonry. The pressure upon each pile in London Bridge has been estimated at 80 tons, or about 5 tons per foot superficial on the entire area, and this is considerably below what the piles would actually carry. The difficulty of applying sufficient dead weight upon piles, to ascertain their bearing powers in equilibrium, has always prevented the formation of any formula or data on which engineers can base their experiments. The piles are driven, and the pressure they must be sustaining is then calculated after the load is on, no maximum having been ascertained. The pressure upon each pile of Waterloo Bridge is probably somewhat less, but still it must amount to at least 68 tons. London Bridge has a close pile sheeting all round the platform, which penetrates about one-third of the distance of the main bearing piles. Waterloo Bridge does not appear to be so protected, yet London Bridge after the removal of the cofferdams settled in every pier from 6 to 10 inches towards the down stream; this was attributable to the entire area of the river substrata finding their proper bearing after the disturbances to which they had been subjected by the piling of the cofferdams and of the centerings. The cofferdam above bridge was in 35 feet of water below low-water mark, and the piles were consequently very deeply driven, and though those which were near to the piers, or could apparently affect them, were not drawn but cut off, the mass of the clay had received a disturbance which settled itself probably once and for ever, and if the bearing areas and the tenacity of the piles are sufficient for the superincumbent pressure, no further settlement need be apprehended.

Collapse of Buildings.

The records of failures in the Middle Ages rather indulge in religious than in practical explanations of the causes, and so we do not gain much practical knowledge from these examples, such as the fall of the towers of Winchester Cathedral in the twelfth century; of Gloucester Cathedral, in 1160; of Worcester Cathedral, in 1175; of Evesham, in 1215; of Dunstable Priory, in 1221; the smaller towers of Worcester Cathedral, in 1222; the tower of Lincoln, in 1244; of Ely Cathedral, in 1322; of Norwich Cathedral, in 1361; and the west front of Hereford Cathedral, in 1786; the central tower at Hereford would have fallen had not its impending ruin been observed and remedied. The old tower of Thurston Church, Suffolk, fell in 1860. Then we have the Chichester tower in 1861. The above small list of towers awakens the thought that special care is needed for all structures that are carried upon piers instead of upon continuous walls. But the description that has been given of the cause of failure in the Chichester tower would have been very applicable to many of the other cases. The lesson derived from the Chichester fall seems to be that rubble masonry should never be used in piers carrying towers or other heavy work; it is a masonry suitable where bulk and weight are main objects, but it is inadmissible where unyielding vigour of pier is to be attained; it also suggests that in any such case a soft kind of stone is scarcely safe even if it be of a sound nature; and the stone forming the facing at Chichester, though in some respects a good stone, was not suitable for a position where a crushing force was the chief force in action. It was from near Binstead, in the Isle of Wight, and it is the only tertiary building stone in England; but if we want a thoroughly good freestone we must get it out of the secondary beds. The stone in the piers of the French Panthéon was of a rather weak quality, but that with which the inner and intermediate domes were formed was tertiary, from the quarries of Conflans, about eighteen miles from Paris, and for which latter purpose it is particularly suitable.

Theory and Practice.

It has been remarked by Professor Willis "that there still remains amongst self-taught practical men too much of the ancient contempt for theory and an overweening and conceited value for facts or practice." This arises, in great measure, from a misconception of terms; the self-taught practical man generally confounds theory with hypothesis, and is unaware of what is really meant by the term theory or science. For if science be correctly defined as "the knowledge of many, orderly and methodically digested and arranged so as to become attainable by one," and the "practical knowledge" of the self-taught man as the personal experience of a single man in a necessarily limited number of cases, lacking the aids to orderly and methodical arrangement and analysis afforded by a mathematical and scientific training, then it follows from such

definitions that "science" includes "practice" in its widest sense; and that the so-called "practice" on which the self-taught man so much prides himself is neither more nor less than an imperfectly methodised contribution to "science." In short, as has been well observed by our ingenious neighbours, "*la théorie c'est le général; la pratique ce sont les soldats*"; and to talk of theory and practice as if each were a complete and rival entity is as absurd as to suppose it possible that an army could be completely and efficiently composed either of officers without private soldiers or of private soldiers without officers. Moreover, in point of fact, no practical man is ever really contented with the narrow basis of his own individual experience, but, on the contrary, he habitually makes use, in every work he carries on, of the formulæ or mathematical generalisations deduced by theorists from the careful consideration and collation of an extended basis of practice. The self-styled practical man is therefore not one who can afford to dispense with science, but one who is restricted in the application of science to construction by being obliged to get his science secondhand. It is true that formulæ, when of established accuracy, are often made use of secondhand for the purpose of saving time, by the scientific engineer as well as by the merely practical man, but the latter labours under the grave disadvantage of being only able to use them mechanically. He is unacquainted with the processes by which they were deduced from facts, and unable to detect or correct any errors they may contain. Still less can he frame fresh ones for himself. Like David with Saul's armour, he has not proved his weapons, and cannot therefore be expected to use them to so much advantage as one who has.

The Roof-Sculpture of Milan Cathedral.

As you walk along those white marble terraces, mounting ever higher, you see below you the rich level plains of Lombardy, teeming with villages and churches and cities, with their long busy white roads, with fields and groves and glistening rivers stretching far away and on into the distance, until at last the dark purple of the horizon lies sharp against the clear circling blue of the sky, and the world seems ended, a perfect circle everywhere, except to the north, for there a veil of white mist conceals it, and far above that mist the snowy summits of Alps upon Alps hang, in their glittering majesty, high up against the sky. Not less silent and unchanging stand the victorious saints, in white and glistening raiment, on countless pinnacles, on every side, above, below and around you. Some of them are leaning on the spear, or sword or cross, by which they died; others bear the palm-branch, which marks them as conquerors. Even without these tokens, and without the angel figures which bear them company, their countenances alone would tell you they are conquerors—conquerors over doubt and sin, over sorrow and pain and death, over themselves; their whole being is satisfied, all the stains and the weariness of their warfare are past and over; they rest as those may rest who have heard the words, "Well done, good and faithful servants." They rest, and yet they watch, as men that wait, without a shadow of impatience, without a shadow of doubt, with all the certainty of those who know in whom they have trusted. You turn again to the towering Alps, and by the side of that steadfast strength, that deep peace, that immoveable faith, even the mountain peaks seem to you weak and unstable. The execution of some amongst these statues is very unequal, but the idea, the truth sought to be expressed, is unmistakable.

Decorated Mouldings.

We sometimes meet with mouldings of much earlier or later date than we should have expected from other characteristic marks in the building, and there are not a few instances in which without the aid of such marks it would be impossible to say whether a moulding is of the fourteenth or the fifteenth century. In fact, this science does not appear capable of more than general treatment, though there is quite enough of uniform system to enable us to apprehend the broad distinctive principles which obtained in the different periods. Generally, then, we observe much greater geometrical precision in drawing both the hollow and the projecting members than prevailed in the preceding style. Segments of circles, both concave and convex, were much used, and there was a softness of blending, a delicacy and gentleness of grouping, an avoidance of strong and violent contrasts of light and shade, which imparted a more pleasing, though much less striking effect. There can be no doubt that the perfection of moulding, as of all architectural detail, was attained in this style. And yet rich Decorated mouldings are of rather rare occurrence. A great many of the finest buildings in this style scarcely afford as good examples of mouldings as the smallest and humblest church of the Early English age. Very often plain chamfers are used in all the windows, doorways and pier arches, while minor parts, such as bases, capitals, sedilia, sepulchral recesses and the like, have fine and elaborate details. It is in this kind of work that we must look for the best mouldings in the Decorated style.

NOTES AND COMMENTS.

SOME time ago a dispute arose between the heritors or property owners in the parish of Kinghorn, in Scotland, and the local Presbytery respecting the parish church. The latter body came to the conclusion that it would be wiser to abandon the existing building and erect a new church, because the alterations and repairs required to make the old church sufficient and serviceable for public worship would cost as much as a new edifice. The heritors, however, objected to the erection of a new church, and preferred to repair the old one. Litigation began, and the Sheriff commissioned Mr. SYDNEY MITCHELL, architect, Edinburgh, to examine the old building, and report as to the cost to make it "sufficient and serviceable for public worship," and also to estimate the cost of erecting a new church. Mr. MITCHELL considers the heritors' offer will not make the church "sufficient and serviceable for public worship." He is, however, of opinion that the present church can be repaired, and that at a less cost than it would take to erect a new church. He proposes very extensive alterations on the present building, both internally and externally. The outlay to accommodate 756 sittings as at present, or 684 as to space now allocated in erecting new churches, would be 1,700*l.*; or for 550 at the wider space, 1,300*l.* The cost of a new church, including expense of site, boundary walls, &c., to accommodate 700 people, he estimates at 3,200*l.*; 550 people, 2,600*l.* The Presbytery have no objection to Mr. MITCHELL's plan to repair the old church being carried out, provided it be remitted to that gentlemen to see the work done according to his report and plans. The heritors prefer to carry out the repairs themselves, but it has been decided that Mr. MITCHELL is to have the charge of the works.

THE series of reproductions of Japanese designs produced by the Librairie de l'Art has been completed. The subjects comprise flowers and plants, birds, animals and fish. They are all taken from fine examples, and the eight parts which are obtainable for twelve francs form a collection that will enable a student to appreciate Japanese skill. The copies of quadrupeds cannot be considered as always successful. Cats, tigers and monkeys appear to be the most suitable models for the Japanese. They have more success when sketching birds, and they are unequalled in suggesting the character of fish. The fine curves that are formed when in motion and the scales appear to have had at all times a fascination for the artists. Apparently too much time cannot be spent by them in elaborating the details of flowers. The dated examples extend from the beginning of the eighteenth century, and all appear to have been produced prior to the introduction of Western notions into Japan. As a corrective to the heaviness of treatment which is too common a result of English teaching, there can be nothing better for ornamentists than an appreciative study of Japanese designs.

THERE is the usual Celtic indifference to consequences apparent in the organisation of the Dublin Fire Brigade. For a city containing so many houses it is believed that twenty-eight firemen are an ample protection. Fortunately many of the buildings are of the flimsiest construction. When one is attacked it quickly collapses, and in that way the risk of an extension of a fire is minimised, and the few men that are available are able to cope with the smouldering *débris*. The fire that broke out in one of the largest drapery shops, or "monster houses," in Henry Street on last Friday morning afforded a lesson to the authorities and the people which should be studied. At 1.14 A.M. intelligence was given, and with commendable activity the operations of the firemen began four minutes afterwards. In about twenty minutes a large part of the building had collapsed, and the efforts of the firemen were concentrated on the preservation of adjoining property. One of the town councillors considered it was "a veritable miracle" that hundreds of lives had not been lost, and the Lord Mayor, whose faith apparently is less simple, said that "whether the result was due to the brigade or to Providence, it was a remarkable thing." Another councillor considered that, owing to the inefficiency of the brigade, the whole street was likely to have been destroyed if the building had not collapsed

immediately. The loss to insurance offices will be enormous, but if they will persist in making little difference between stable and unsound construction they must abide by the results. In the Dublin fire the building offered so little resistance that the firemen were beaten back within five minutes after the hose was laid down, and the captain considered it was hopeless to attempt saving the place. The Lord Mayor proposes, as a means to insure the city, that fifty policemen should be taught the firemen's drill, but when "monster houses" become ashes in a few minutes there is not much chance for ordinary houses, although a few firemen and auxiliaries may be present.

It is satisfactory to find that one public body is opposed to the indiscriminate adoption of the principle of giving the highest rate of wages to workmen, regardless of the conditions on which the contractor based his tender. A report had been sent in by a special committee of the Leeds County Council in favour of the introduction of clauses regulating wages, hours and sub-letting in all contracts. The Leeds Builders' Exchange Club, having considered the proposal, passed the following resolution without delay:—"That this meeting is of opinion that the clauses as drafted by the town clerk for insertion in all contracts entered into with the Corporation are most arbitrary and one-sided. They hold that it would have been better, before pandering to the labour party, if the contractors or their representative bodies had been consulted, so that both sides of the question might have been fairly considered. More especially do they object to clause 4, which provides for the investigation of a tradesman's books. This clause they consider to be inquisitorial and a flagrant violation of the right of free contract." The Leeds Master Builders' Association also protested against some of the clauses, and expressed the opinion that if the proposals of the committee were persisted in the Corporation would have to go outside of Leeds for contractors, and even then would probably have great difficulty in obtaining them. It further suggested that the Council should submit to the Association a form of contract for their consideration. In the face of such determined opposition, what could a Council do? An effort was made to uphold the policy proposed, but finally it was decided that the question should be referred back to the committee, who should be instructed to consult with the masters' organisations, as well as those of the men, before submitting the rules to the Council again. We have often recommended builders and other employers to assert their power, instead of allowing themselves to be ignored by local authorities. The protests in Leeds have at once overwhelmed the Council, and the course of action which succeeded there would not be a failure in other places.

EVERYTHING in the best of worlds might be supposed to be going wrong. On all sides persons put themselves in evidence as saviours of their fellows. This has been a remunerative occupation for many who have an ambition to make money and notoriety for themselves, but which they are too lazy, or have not the ability or perseverance to secure in a legitimate way. At present there is an opening for other heroes to rise up and save us from such friends. Outside of these matters, however, there is a good deal of injustice done to professional men; but if there is a real grievance it is worth no man's time to work for reform. One case in point is that public bodies, institutions, &c., having to rely on officials for conducting routine work, and often special work that can only be done by men trained by costly education, have now and again to fill up vacancies. The usual way when an appointment becomes vacant is to advertise for applicants. In many cases this simply results in utter disappointment to the applicants. Often these corporations in their advertisements should say that none but local men are to apply. Those responsible for filling up appointments should know whether they intend to get applications from the most eminent men in the country, only to pass them over in favour of one of their own subordinate officials. It may not be intended, but it is scarcely less than a gratuitous insult to men of eminence in their profession to act so.

THE ROYAL COLLEGE OF MUSIC, SOUTH KENSINGTON.

THE new building of the Royal College of Music was opened by H.R.H. the Prince of WALES, the president, in the name of Her Majesty the QUEEN, on Wednesday, May 2. It stands almost midway between the Albert Hall on the north and the Imperial Institute on the south, on a broad road running from Princes Gate to Queen's Gate, and called the Prince Consort Road. The college is built of red brick, with bands and dressings of Weldon stone, and the roofs are covered with green slate. The style is Renaissance, freely treated. The cost of the building has been defrayed by a sum of 45,000*l.* munificently presented to the Prince of WALES for the purpose by Mr. SAMSON FOX, M.Inst.C.E., of Leeds, in 1891. The decorations of the entrance hall have been carried out at Mr. FOX's cost by a further donation of 1,000*l.*

The college has been erected from the designs of Sir A. W. BLOMFIELD, A.R.A., by Mr. THOMPSON, of Peterborough, on a plot of ground granted to the college at a nominal rent by the Royal Commissioners of 1851. It is divided into two wings, one for the male and the other for the female pupils. These have separate entrances, staircases and lifts, but are connected on each floor except the top by a corridor running from end to end of the building. The main entrance for the public is in the centre, leading into an entrance hall. Immediately in front of a visitor on entering is the general office for inquiries, &c., on the right are the offices and private rooms of the director and registrar, and on the left council and committee-rooms, waiting-rooms, library, &c.

In the sub-basement are the kitchen, the dining-rooms for professors, pupils and servants, and offices; on the basement, first, second, and third floors are the requisite number of classrooms of varying sizes, and in the upper part of the towers, which form a conspicuous feature at each end of the building, are placed the organ-rooms.

The building occupies the portion of the ground immediately abutting on the Prince Consort Road, and space is left in the rear for the erection of a theatre and concert-room, as well as for other additions as the number of pupils increases. Owing to the fact that the ground falls rapidly away from the front, the building has a basement and sub-basement below the ground floor, both entirely above ground on the south front and at the sides.

The theatre already mentioned will, it is hoped, be erected at no distant date. It will be planned to serve also for a lecture-room and for orchestral concerts, and will be placed immediately at the back of the central offices on the spot now occupied by the temporary hall, with ample means of easy and direct access and exit by the front entrances. Underneath the theatre, which will be entered on the level of the ground floor, will be large rehearsal-rooms, dressing-rooms, &c. Mr. OLROYD, of Leeds, was entrusted with the ventilation, &c. Immediately below the roof is a noble room running nearly the whole length of the building, which it is hoped to occupy shortly with a collection of musical objects.

In a room immediately behind the temporary hall is the very valuable and unique Donaldson Museum of historical musical instruments formed by Mr. GEORGE DONALDSON, and presented by him to the Prince of WALES for the permanent use of the college.

The statues of the Prince and Princess of WALES in the entrance hall, and the bust of Mr. FOX, were executed by the late Prince VICTOR OF HOHENLOHE. The statue of the Princess was presented to the college by a committee of ladies through the Marchioness of SALISBURY, president of the committee; and that of the Prince of WALES by a committee of gentlemen through the Earl of LATHOM, the chairman. The bust of Mr. FOX was executed for the council of the college. In the council-room is a marble bust of the late Duke of CLARENCE, executed for Mr. SAMSON FOX by Mr. J. S. WEBBER, the sculptor, of Harrogate, and presented by Mr. FOX to His Royal Highness the Prince of WALES as president of the college.

THE MARKET PLACE, SAFFRON WALDEN.

LANGLEY, PUTNEY HEATH.

THIS house stands in a good position upon the Kingston Road, close to Putney Heath. It is constructed of red brick facings, the upper part of the walls

and roof being tiled. The windows have wood frames and mullions and iron casements, and are glazed with lead lights. The ground floor provides three sitting-rooms, with separate garden entrance from the hall, also kitchen and offices, as there is no basement. On the first floor there are four bedrooms, dressing-room, bath-room, &c., whilst the top floor has two bedrooms, with large day and night nurseries, h.m.c., and box-room.

The architect was Mr. WALTER E. HEWITT, A.R.I.B.A., of 7 Great College Street, Westminster, and the contractors Messrs. GEORGE CANDLER & SONS, of Brixton, who executed the work with great care.

RED BRANCH HOUSE, WIMBLEDON.

THIS building is the result of an attempt to design a good, plain, sensible family residence, giving a large amount of accommodation for a small outlay.

The house, which is now approaching completion, is situated on a somewhat cramped site in Lauriston Road, Wimbledon, and the plan has been considerably affected in consequence, and a basement for coals, wine, stores, &c., made necessary. On the ground floor there are four sitting-rooms, hall with garden entrance and lavatories, kitchen and offices. The first floor has, including day and night nurseries, six bedrooms and dressing-room, with bath, also separate bathroom, linen-room, h.m.c., &c. The top floor provides four bedrooms, h.m.c., box-rooms, &c. A main staircase gives access from the ground to the first floor, while a secondary staircase reaches from the basement to the top floor.

One great object kept in view was to minimise the servants' labour, and to effect this a lift has been provided for carrying coals, boots, &c., from basement to top floor.

Hot and cold water can be drawn on each floor, and brass fittings have been carefully avoided as far as possible throughout, the door furniture being of ebony, dull polished, and the fender-curbs to the sitting-rooms of marble, with pitch-pine floors wax polished.

The elevations are of simple character, it being intended that the walls should be draped with nature's covering in the shape of creepers.

The facings are of dark brindled Horsham stocks, with red-brick pilasters, arches, cills, bays and chimney-stacks.

The roof is covered with green Tilberthwaite Westmoreland slates, and has a very wide projecting eaves cornice.

Mr. WALTER E. HEWITT, A.R.I.B.A., of 7 Great College Street, Westminster, and of Wimbledon, is the architect.

The contract sum was 2,485*l.*, and the work is being efficiently carried out by Messrs. E. P. BULLED & Co., of Croydon.

LIVERPOOL ARCHITECTURAL SOCIETY.

THE annual general meeting of the forty-sixth session of the Liverpool Architectural Society was held on Monday, Mr. Henry Hartley presiding. The following officers were re-elected:—Mr. Henry Hartley, president; Mr. A. Culshaw and Mr. H. W. Keef, vice-presidents; Mr. J. W. Blakey, librarian; Mr. Jas. Dod, treasurer; and Mr. Henry L. Beckwith, secretary. The President, in his address, said that during the past year they had done much towards advancing the influence of their Society and establishing its position among them. It was a cause of great gratification to hear of the establishment of a chair of architecture at the University College. The last remarks he made on the subject were hopeful but uncertain, but now at the close of that session they were able to refer to it as an accomplished fact. They were now only awaiting the appointment of a professor to make it complete. The senate of the college in all probability during the next few days would appoint a professor. The medical school had worked and striven for two additional chairs, which, through the liberality of Lord Derby and Mr. George Holt, had now been provided. He alluded to this to show that the chair of architecture had not been singular in the period of its waiting. In view of what had been accomplished, he suggested that all members of the profession should endeavour to make the new chair successful by inducing pupils to attend the lectures. Mr. J. M. Hay remarked that the professor of architecture should be a man not only possessing good sound practical knowledge, but also a thorough theoretical acquaintance with architecture as a fine art.

THE PRESIDENT ON THE ACADEMY EXHIBITION.

IN his final speech at the Royal Academy banquet on Saturday Sir Frederick Leighton said:—More fortunate than last year at this season I have to note to-day the loss of one only among the acting members of this body—that of a sculptor of much repute, whose first steps in art were taken under the stimulating guidance of a powerful artist whose name is a just boast to the green island which gave him birth—John Henry Foley. Less vigorous, no doubt, than his eminent master, Charles Bell Birch yet imparted to his works great life and spirit, and the charm of a facile and picturesque execution, and even in this day of renovation and growing strength in the practice of that stately art, sculpture in this country will miss him in its ranks. From amongst the honorary retired Associates of this body another sculptor, W. F. Woodington, has been removed by death—an artist whom for many years age and infirmity had withdrawn altogether from public ken. The work of his vigorous prime may still be appreciated on the base of the Nelson column in Trafalgar Square. But whilst our active ranks have suffered diminution by one death only within the year, two justly conspicuous men have fallen in the wider field of English art, both of them men of marked and distinctive personality—both painters, both to me deeply interesting. One of them, Albert Moore, an unbending upholder of the sufficiency in art of whatever is nobly decorative, was a devoted student of the severer graces of Hellenic art, and married in his works spontaneous and supple gesture with forms of chaste sobriety, clothing them in delicately harmonious tones, of which the studied arrangement announced to the first glance the refined idiosyncrasy of his artistic temper. How great a psychological contrast is offered to the placid charm of these works by the fervour of those of the artist whom I have next to name, an artist of strong intellectual bent and steeped in human sympathies, the originator of the movement which startled humdrum people forty or more years ago, and produced a most interesting phase of English art—I speak of Ford Madox Brown, who recently passed away in the fulness of respected years and in the unabated intensity of his convictions. I am not here to defend in every point the nature of those convictions; I am not wholly at one with them. Ardently admired by many, stimulating and highly interesting to a still larger circle of the intelligent, who did not, perhaps, wholly follow his doctrine, he was not altogether acceptable to the wider and less cultured public which so largely influences the creation of that empty and fickle thing called popularity; for there was that in his work which was apt to rouse the uneasy dread of the not usual which mostly marks the middling mind. But this, apart from his technical endowments and rare vividness of dramatic vision, I fearlessly affirm—in the work of no English hand burns a more ardent sympathy with human emotion, or is revealed a more subtle observation of the outward signs and gestures by which these emotions are conveyed. The artistic memories which associate themselves in our minds with Madox Brown and his concentrated energies bring vividly before us as we look upon the walls of this exhibition, or glance in thought over the wider area of contemporary production in England, the changes which two score years have wrought in the character and tendencies of art in this country. As we wander through these, I rejoice to say, more than ever catholic and hospitable galleries, within which the still young unfold this year so much vitality and promise—and gentlemen, to us, the old, there is, believe me, no gladder sight or one more full of comfort—we are struck, not with a concentration of aim or purpose in the school, but rather with a radiation and scattering of effort in innumerable directions. No one, I think, can fail to observe the extraordinary differences of mood and manner shown in the works that have found equal shelter on these walls, and the wide multiplicity of individual personalities which they proclaim. In the range of figure-painting, for instance, what variety of subject as well as of temper meets us. We see not historic or domestic scenes alone—not alone scenes in which the rhythmic dream of beauty and of style is aimed at—but works also not a few of purely imaginative character, fanciful, mythological, allegorical, symbolic, amongst which latter one especially, I think, is dominant in its powerful originality and the weird charm of its decorative pomp. In the region of landscape, no less, every mood is touched and every association evoked, from the infinite solemnity of the silent Arctic solitudes to the infinite sweetness of a Surrey homestead nestling within its sheltered nook, or the laughter of the flower-fields of the Alps in June. What various temperament, too, we note in the expressional use of tone and colour—here, vivid and vibratory; there, grave and soberly subdued. In sculpture, again, though the display is numerically small, there are amongst various good works some that are salient. I will name one by a late *alumnus* of these schools, which has passed into the hands of the nation, and, in another room, the dazzling sketch of a monument, deeply

pathetic in its occasion, and of which this country will, I believe, be justly and lastingly proud. On all hands, then, in sum, we are conscious of Life. With it, we are aware in much of the art of the day of a certain feverish tentativeness—a grouping, as it were, sometimes after a new spirit, sometimes after a repristination of the old in a modern form; but everywhere, I repeat, we see Life. And, gentlemen, to those who, like myself, believe in the necessary triumph of the higher over the less high, in the eventual sure survival of the wholesome and the strong, and in the falling away and withering of the vicious or the morbid, this sign is the most welcome, the most inspiring and the most hopeful sign of all.

CHURCH BELLS.*

PERHAPS the earliest bells of which we have any record are the small bells which were hung from the edge of the ephod worn by the high priest, of which Moses speaks. Bells do not appear to have been introduced into Christian worship until the fifth century. Paulinus, Bishop of Nola, in Campania, is generally credited with their invention or introduction into church use. These early bells were hand-bells, and were made of iron plates beaten into four-sided shapes, and welded or pinned. These were called *No'æ*, and the larger bells *Campanæ*. Church bells are, however, also called "*Signa*" in Mediaeval documents. Bronze bells were found by Mr. Layard at Nineveh; they have also been found in Indian cromlechs and cairns, and small bells have been found in Egypt of the Ptolemaean period.

Mr. Westwood, in "*Arch Cambrensis*," speaks of the Irish in their early attempts to Christianise Iceland carrying with them Irish books and bells. The term "*tintinnabulum*" was given to a set of small bells of different tones set in a row and struck by a hammer, but we soon find the *Nola*, or hand-bell, generally called *tintinnabulum*. Some of these, of great antiquity, are now extant in Ireland, North Wales and Scotland. Bells appear to have been used in Ireland as early as the time of St. Patrick (died 493). Giraldus Cambrensis says that "both the laity and clergy in Ireland, Scotland and Wales held in such veneration certain portable bells that they were more afraid of swearing falsely by them than by the Gospels, because of some hidden and miraculous power with which they were gifted, and by the vengeance of the saint, to whom they were particularly pleasing, their despisers and transgressors were severely punished." When St. Teilo was raised to the episcopal dignity we are informed by the "*Liber Landavensis*" that "the people presented him with a bell that was more famous than great, more valuable in reality than appearance, because it condemned the perjured, it healed the sick, and, what appeared more wonderful, it sounded every hour without anyone moving it." This bell was called "*Bangu*," a name which later on was given to a hand-bell kept in all the Welsh churches, and which, among other uses, always took part in funeral rites. The clerk or sexton took it to the house of the deceased on the day of the funeral; when the procession started a Psalm was sung, then the bellman sounded the bell in a solemn manner for some time, when another Psalm was sung, and again sounded it at intervals until the funeral arrived at the church. It is the custom at Oxford for a bellman to precede the funeral procession of any member of a college, sounding the bell at intervals until the corpse arrives at the place of interment. The late Professor Westwood, in writing of a bell of bronze which has been kept in the church of Llangwynnodl, Carnarvonshire, says that the clerk before a funeral used to go round the churchyard ringing the bell. He further says that there are persons still living who remember that in Carnarvon a bell used to be rung through all the streets to give notice of an approaching funeral. At Holywell, Flintshire, a person goes round the town ringing a bell to call the inhabitants to church, from which he is called the walking steeple. The bell at Llangwynnodl has serpents' heads for the terminations of the handle where it is attached to the bell. The bell is flat-sided, and has a clapper formed of a long iron stem, with a ring of the same metal fastened near its extremity, and suspended from a hoop of metal fixed within the upper part of the bell beneath the handle.

In the Journal of the Archaeological Institute, vol. 5, p. 330, is described an ancient bronze bell which was found at Marden, Herefordshire, in cleaning out a pond. The pond is only a few yards from the church built on the spot where the body of St. Ethelbert, murdered by Offa, was said to have been deposited. The site of the vicarage has been asserted to have been that of Offa's palace. The bell appears to have been formed of a sheet of bell metal which had been hammered into shape and rivetted. The handle at the top is rounded beneath for the hand; the clapper is gone, but there is a loop inside from which it was suspended. It is 12 inches in height, without the handle, 7½ inches across the bottom in the widest and 5 inches

* A paper read by Mr. S. S. Stanley, at the annual meeting of the Warwickshire Archæologists and Naturalists' Field Club.

in the narrowest diameter; the upper part is 5 inches in the largest and 3 inches in the narrowest. The circumference at the top is 15 inches, and at the bottom 24½ inches. The rudeness of this bell, as well as the proximity of the locality to Wales, would lead to the supposition that it is a relic of the British rather than of the Anglo-Saxon Church, strengthened by the description of a similar bell preserved at Birnie, in Scotland, the Christians of which country were disciples of the early Irish Church, between which and the British, on the authority of the Venerable Bede, there were no material distinctions. Two bells of a similarly early make have been found at Llandisant and Llanrhyddlad, and were probably used in the celebration of mass. The bell of St. Kentigern, the great apostle of Strathclyde, after forming for centuries a prominent feature in the armorial bearings of the archiepiscopal see, still figures in the modern arms of the city of Glasgow. Many other Celtic and very ancient bells are figured and described by the Rev. H. T. Ellacombe in his treatise on the bells of the Church. There is a figure of a bell-ringer on a Saxon font from Hutton Cranswick, now in the York Museum, and on a column of a chancel arch at Stoke Dry, Rutland. The bell-ringer on the font is supposed to symbolise the devil driven out at baptism. Quadrangular bells of the Celtic type are to be seen sculptured on the crosses at Winwick, Lancashire, and Kilcullen, Wicklow; also on the lintel of a doorway at Glendalough, Wicklow. I have seen in the possession of Sir Henry Dryden a similar bell to these ancient Celtic bells which I have described, but its history was lost. These bells are precisely similar to the small bell now used for attaching to the neck of a sheep, the bell-wether of the flock, on the Downs. There was another sort of Irish bell of a pear shape, called "Crotal," several of which are now in the museum of the Royal Irish Academy.

I now come to speak of large bells, and I might preface my remarks by an allusion to the curfew. The sounding of an "ignitegium" was a custom which prevailed in Spain, Italy and Scotland, and most of the countries of Europe, when it was instituted by King Alfred the Great at Oxford, and later on more rigidly enforced by William the Conqueror. The law was abolished by Henry I. in 1100. Pope Sabinianus (A.D. 604), having ordered the hours to be sounded on the bells, is thought to have introduced the use of the Campanæ, or Signa, as the large bells were called, into churches.

The Westminster clock bell, the largest we have, was cast by George Mears in 1857; it weighs 13 tons 10 cwt. 3 quarters 15 lbs. It was designed by Edward Beckett Denison, Q.C. the ornamentation being designed by the late Arthur Ashpitel, F.S.A. This bell is commonly known as Big Ben of Westminster. Peter of York is the next largest. It was cast by Messrs. Mears in 1845, and weighs 12½ tons. The Mighty Tom of Oxford is the next; it weighs 7 tons 12 cwt., and was cast in 1681 by Keen, or King, a Woodstock bellfounder. The great bell of the cathedral of Lincoln was cast by Thomas Mears in 1834, and weighs 5 tons 8 cwt. The great bell of St. Paul's, inscribed "Richard Phelps made me, 1716," weighs 5 tons 4 cwt. The Great Peter, of Exeter, is reported to weigh 6 tons 5 cwt., and was re-cast in 1676 by Thomas Purdue. Great Peter of the cathedral at Gloucester is thought to have been founded early in the sixteenth century. It has the founder's escutcheon (three bells) and the arms of the church (a sword and two keys, saltire) and the inscription, "Me fecit fieri Conventus nomine Petri." Besides this bell—the clock—Gloucester has eight bells, of which five or six date from 1390-1418, and were founded by Robert Burford, of London. No. 5 is a Mary bell. Great Peter weighs upwards of 2 tons 18 cwt. The Moscow bell is said to weigh 220 tons, and one at Troitzkoi 171 tons. A bell of early in the fifteenth century forms the third bell of St. John's, Coventry. It bears the inscription, "Henricus Dodenhale me fieri fecit," and on the crown "C ST. JOHIS," which probably stands for Campana Sancti Johannis. At St. Chad's Church, Cloughton Lane, there is a bell which is thought to be of the date 1296. It bears inscribed thus, "ANNO DNI M CC NONO AI +," the letter "v" is reversed. At Cold Ashby, Northamptonshire, one is inscribed "+ MARIA VOCOR ANO DNI M CCC XVII." Two richly-ornamented bells, dated 1323, are in the tower of St. Mary, Somercotes, Lincolnshire. Bells of the fourteenth century rarely bear their date, but generally have an invocation to some saint and the founder's arms or trade mark. Sometimes bells have the alphabet, or some portion of it, instead of inscription. Such a bell may be seen at Ryton in this county. About thirty years ago, on taking down a bell for repairs to the steeple of the church of Ornolac, near Ussat-les-Baines (Ariège), it was found to bear the date 1079, and must, consequently, be one of the oldest hanging bells in Christendom.

The remarkably fine bells of Limerick were originally brought from Italy; they had been manufactured by a young native, and finished after the toil of many years, and he prided himself upon his work. They were subsequently purchased by the prior of a neighbouring convent, and, with the profits of this sale, the young Italian procured a little villa, where he

had the pleasure of hearing the sound of his bells from the convent cliff, and of growing old in the bosom of domestic happiness. This, however, was not to continue. In some of those broils, whether civil or foreign, which are the undying worm in the peace of a foreign land, the good Italian was a sufferer among many. He lost his all, and, after the passing of the storm, found himself preserved alone, his fortune, friends, family and home having perished. The convent in which the bells, the *chef-d'œuvre* of his skill, were hung was razed to the earth, and these last sold to be carried away to another land. The poor unfortunate, haunted by his memories and deserted by his hopes, became a wanderer over Europe. His hair grew grey and his heart withered before he again found a home or a friend. In this desolation of spirit he formed the resolution of seeking the place to which these treasures of his memory had been finally borne. He sailed for Ireland; proceeded up the Shannon; the vessel anchored in the pool near Limerick, and he hired a small boat for the purpose of landing. The city was now before him, and he beheld St. Mary's steeple lifting its turreted head above the smoke and mist of the old town. He sat in the stern and looked fondly towards it. It was an evening so calm and beautiful as to remind him of his own native haven in the sweetest time of the year—the death of the spring. The broad stream appeared like one smooth mirror, and the little boat glided through it with almost noiseless expedition. On a sudden, amid the stillness, the bells tolled from the cathedral; the rowers rested on their oars, and the boat went forward with the impulse it had received. The old Italian looked towards the city, crossed his arms on his breast and lay back in his seat; home, happiness, sound recollections, friends, family—all were in the sound, and went with it to his breast. When the rowers looked round they beheld him with his face turned towards the cathedral, but his eyes were closed, and when they landed they found his body cold.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

RICKMAN'S LETTERS ON THE ARCHITECTURE OF FRANCE AND ENGLAND.

THE little book called "An Attempt to Discriminate the Styles of Architecture in England from the Conquest to the Reformation," by Thomas Rickman, is always likely to be treated with reverence as one of the classics of English architectural literature. Originally it was only a magazine article, and a copy appears very slight and, to those who judge of value by bulk, unimportant if compared with one of Mr. Parker's editions. Several years after the appearance of the "Attempt" Mr. Rickman composed some letters comparing the English styles with those of France. They were afterwards added to some editions of the little book on English work. But they were omitted from Mr. Parker's edition of 1862. Subsequently the letters were used as an introduction to a later edition. Then it was decided to make them a part of a separate work, which never appeared. In the edition of 1881, which we believe is the latest, there is a note relating to them, and the reader is referred to the appendix for them, but no appendix of the kind is found in the volume. Rickman's letters may therefore be classed among the puzzles of bibliographers. They have interest on that account.

But the value of the letters and the "Attempt" should not be determined by interest of that kind, or by the amount of information contained in them. The difficulties of the writer in their composition should also be taken into account. In the early part of the century it was no easy or inexpensive task to travel through the country to compare buildings. Rickman was compelled to be satisfied with data that nowadays would be considered scanty. But like Dalton, Young, Wells, Watt and other students of science, Rickman was able to husband his resources and make a little go far. Modern students can have the command of as many representations of buildings as they desire, and photography enables them to have the advantage of the utmost accuracy of detail, but how few men have the power to classify the facts and to draw conclusions from them like Rickman? The letters we publish reveal his peculiar skill more plainly than the "Attempt." He was a stranger in France, and his acquaintance was limited to one part of it. Few as were his excursions, they afforded him sufficient evidence about the relations between English Gothic and French Gothic, and, as we shall see, his continental experience gave him a new zest for the study of the buildings which he could find in England. It is not necessary to delay the reader by further remarks.

LETTER I.

Birmingham: 10 mo. 12, 1832.

Having, in company with my friend the Reverend William Whewell, of Trinity College, Cambridge, spent a few weeks in examining the ecclesiastical edifices in Picardy and Normandy, and having conferred with Messrs. Le Prevost of Rouen, De Caumont of Caen and Lambert of Bayeux, all active and zealous members of the Society of Antiquaries of Normandy, I am desirous of laying before the Society some account of the results of this examination, if the Society think it worthy of their notice.

I propose dividing the subjects into a series of short papers, each of which may in some degree be considered complete in itself, and be of such a length only as may excite, but not fatigue, the attention.

In the present communication I intend to state the extent of country visited, the number and character of the buildings examined, and a few general remarks on the more striking differences which at once attract attention in passing through Picardy and Normandy.

In the first edition of my essay on English architecture, published in 1817, I remarked that "in every instance which had come under my notice of buildings on the Continent, a mixture, more or less exact or remote, according to circumstances, of Italian composition in some part or other is present, and that I had little doubt that a very attentive examination of the continental buildings called Gothic would enable an architect to lay down the regulations of the French, Flemish, Spanish, German and Italian styles which were in use when the English flourished in England," and it is with great pleasure I find myself enabled by this journey to go some way towards this conclusion with respect to that part of France, at least, which was included in this tour.

The line of country visited may be thus briefly intimated:—From Dover to Calais, Boulogne, Abbeville, Amiens, Beauvais, Rouen, Jumièges, Evreux, Lisieux, Caen, Bayeux, St. Lo, Coutances, Carentan, Isigny, Honfleur, Pont Audemer, Caudebec, Lillebonne, Harfleur, Havre de Grace, and thence to Southampton.

In the course of the journey notes were taken of four edifices of Roman work, or of dates before anno 1000; fourteen cathedrals or collegiate churches; forty-three larger churches in towns; fifty smaller churches in towns and villages; fourteen domestic edifices and civil edifices; six smaller edifices, shrines and details.

In this number of above one hundred churches, only nine ancient fonts were discovered, all the rest which were seen being modern, and mostly of one species of marble called, in Normandy, Flemish marble, but we had no clear account whence it came.

With respect to the general features of difference striking an English eye on visiting the ecclesiastical buildings in Picardy and Normandy, the most prominent are:—

1. The want of clearness of outline, occasioned by the great breadth of the large churches, from their mostly having two aisles on each side the nave, and the great magnitude and grouping of the flying buttresses. Of this want of outline perhaps the cathedral of Beauvais (though it has very fine portions) is the most conspicuous example, for having no nave, only choir and transepts, it looks at a distance a heavy lump, and it is only when near enough to distinguish some of its admirable details that it can be properly appreciated.

2. The great interior height of the nave, and often of the aisles, in proportion to their breadth; this feature, though not constant, is very general, and is often from one and a half to nearly double the usual English proportions of height as compared to breadth.

3. The very general termination of the east end of large churches (and also very many small ones) in a circular or polygonal apsis; this, with the chapels and aisle surrounding these apses, tends very much (aided by the lofty and extensive flying buttresses) to give that lumpishness mentioned above.

4. Another, though not perhaps so prominent a feature, is the greater height of the windows from the floor. In only one or two at most of the whole number of churches inspected, could the windows be looked into by a person outside.

All these differences from English appearances are very prominent, and strike the eye at once of the most rapid and inexperienced traveller; but the others, which we have yet to enumerate, are equally noticeable to the eye accustomed to the examination and comparison of details.

Of these minor differences may be stated:—

1. The unfinished or irregular terminations of towers; sometimes two nearly alike, but with different tops; sometimes one tower despoiled of its ancient cornice, parapet, and pinnacles, and a very ugly modern slate roof put on it. I am not sure that we saw more than one or two towers in the whole line which were perfect in these respects, and many were terminated in a way which, though not unknown in England, is very uncommon, viz. the tower on two sides has high gables, and is roofed from these with a common house ridge roof. This sort

of roof is called a pack-saddle roof. This unsightly mode seems to be often original, but perhaps as often a mutilation. The stone spires, which are numerous, are more fortunate and in general tolerably preserved.

2. The total absence, in all our route, of a cut battlement, either real, when used as a parapet, or apparent, when used ornamentally.

One small piece, apparently very recent, on a wall in the court of the Bishop's Palace at Evreux, was the only portion we saw. Plain parapets are common, and perhaps pierced parapets in good churches still more so; but there are still very many village churches with dripping eaves.

3. The very great predominance of wheel windows, most of them large and of elaborate tracery.

4. The smallness of the exterior bases and their very trifling projection is remarkable, as is also the great boldness and projection of the few which form exceptions to this rule.

All the above are differences constantly occurring and very apparent; but there are many more to be stated, when we come to compare edifices of similar dates and characters, as worked at the same time in each country.

It may be proper in these preliminary remarks to state that in order to prevent confusion I call the entrance end of a church the west, and the altar end the east; but that, in very many instances, churches in our route were found built so much across the compass, that it is sometimes difficult to make out which is east, as the number of central towers in small churches not cruciform is considerable. In the city of Caen this deviation is so great that some of the churches are in this respect directly opposed to others.

As the nature of the stone used in the districts which we have examined seems to have had considerable influence on the design of many churches, and particularly on the ornamental parts, it will be right to notice that from Abbeville to Evreux, and perhaps even further, the larger churches are composed of a white stone, which may be scratched by the nail, and works very easily, yet seems of great durability; as works of great delicacy, executed four and five hundred years ago, and even more, are now quite fresh and perfect.

This stone seems a sort of indurated chalk, and is of different hardness in different places; it is mixed in buildings with some of the oolites from Caen and other places, and is singularly adapted for the rich and elaborate tracery, niche-work, foliage and other embellishments of the later French styles.

About Caen and Bayeux that beautiful stone called Caen stone, of which so much was once brought to England, is generally used; and of it or similar stone is much of the early Norman work constructed, some of which is as perfect as when first cut.

In the village churches we find stone of various descriptions; sandstone, limestone and other stones of the locality used mixed with the Caen and other stones of that description, which are used for the mouldings and more delicate portions of the building.

At Amiens, and some other places, a very hard dark stone has been used for plinths and bases. From Bayeux to Coutances a hard stone of very slaty texture is used in small pieces, little larger than the pieces of ragstone used in Northamptonshire, at Brixworth and other places.

In several village churches and the smaller churches in towns this slaty stone and other materials are laid in the way called herringbone masonry, but this construction does not seem always to be very ancient.

Having thus described the route taken, and noticed such matters as apply pretty much to all the buildings visited, I intend in future papers to enter into particular descriptions and comparisons.—I remain, thine truly, THOMAS RICKMAN.

LETTER II.

I now resume the account of the buildings, &c., in Normandy and Picardy, and have taken the fonts I have found for the subject of the present communication.

In the whole number of churches visited (upwards of one hundred) only nine ancient fonts were seen so as to be drawn. There might be a few more in churches we could not get into, but judging from what we did find, I apprehend not many.

A large number of the fonts, whether ancient or modern, have covers, most of which are poor and plain, and in general carefully locked. As before noticed, nearly all the modern fonts are of marble, mostly of one description, called Flemish marble. They are very commonly oval, and some are divided into two basins by a division of marble.

Of the nine fonts I now exhibit sketches. They are not perhaps quite exact representations, but are, I trust, near enough to be understood. Taking them as near as may be in their apparent order of dates they are:—

1. Breteuil (between Amiens and Beauvais). This font is of a shape not uncommon in England. It has a large central bowl, with twelve small shafts and capitals with plain leaves, and the base so common in Early English work. This font is

in very good preservation, and the tool-marks visible, but it is painted.

2. Subles (between Bayeux and St. Lo). The character and shape of this font are not uncommon in England. Its form is graceful and simple, and its mouldings and the arrangements at the corners of the foot give its date.

3. Vaucelles (near Bayeux, and not far from Subles). This font very much resembles the last, but from its mouldings seems a little later.

4. St. George de Bocheville (near Rouen). This is a large and very fine Norman church, with much of later work in various parts, with which this font harmonises. Here, as in the two last noticed fonts, there is a plain bowl on an upright foot, but diversified here by having some of the parts octagonal instead of being all circular, as in the two last.

5. Jumièges (the parish church near the abbey, not far from Rouen). This font is a curious one, being very different in shape from any of the former examples, and harmonising with various fonts of the same shape in Lincolnshire and some other counties. It is also cut in the same way, with flat fillets and shallow panels, with plain slopes for mouldings, and the panelling varied in the different sides. The font at Haydor, in Lincolnshire, is much like this. I consider this font clearly of Decorated character.

6. Duclair (on the Seine, near Rouen). This church is a curious one of various dates, so that it is not very easy to make out the date of the font by analogy. The hour-glass shape of

this font has few, if any, resemblances in England. Its mouldings are not very decisive, but I think it as late if not later than the last example. It may even be later still, but I have no reason to think it modern.

7. Carentan (between Coutances and Cherbourg). I measured this font carefully, and have drawn it geometrically to a scale of 1 inch to a foot. It is composed of several pieces, and may possibly be composed of several fragments. It is circular, and looks very much as if the font had been reversed, and the bowl added at a later date. Anomalies not uncommon in England, of which a church in York has a font which is a curious instance.

8. Ifs (near Caen). The shape of this font is not very uncommon in England, and it also by its form assimilates with the hour-glass shape at Duclair, but here the mouldings are clear and have an appearance of rather late Decorated character.

9. Haute Allemagne (the next parish to Ifs, and near Caen). The form of this font is still more common in England than the last; and, but that the neck moulding has a Decorated character, it might pass for an English Perpendicular font. I think it may be a little before, or perhaps a little after, A.D. 1400.

I fear this account of French fonts will appear a very meagre one; but comprising, as it does, all the ancient ones I

found, I shall feel very much obliged if any members of the Society who possess the means of enlarging the list will favour me with a sight of their sketches, to enable me to add to the number, and thus aid me in making what I wish to do, a more minute and extensive comparison than has yet been made of English and French architecture.—I remain, thine truly,

THOMAS RICKMAN.

At Pont Audemer are two churches, St. Germain and St. Catherine. In the former is a large font, which might be, and I am inclined to think was, ancient, but it was covered with a cloth. At St. Catherine's, the greatest part of which is of very late date and very elaborate workmanship, the font is shut in a chapel, and I could only see a small part of it below a cloth, and it appeared to be of the date and character of the church, but I could not see enough of it to draw it.

(To be continued.)

THE GHIZEH MUSEUM.

IT is announced by the *Times* that the Egyptian Government intend to expend 150,000*l.* for the construction of a new museum to contain the Ghizeh collection. From the following statement by Mr. Henry Wallis it would appear that the treasures in the museum are liable to a new danger, and that a secure building cannot be provided too soon:—

Shortly after the removal of the collection of Egyptian antiquities from Boulak to Ghizeh a daring attempt was made to secure what to the projectors would have been the most valuable objects in the museum. The plan, in brief, was to seize the jewellery and ignite the palace by means of petroleum, and then in the confusion thus created the robbers calculated on escaping with their plunder. It is to a similar danger that the museum—standing alone, distant from Cairo, and in a building composed of inflammable materials and of fragile construction—has always been subject.

Within the last few weeks, however, the risk has been considerably increased. The recent excavation of the director, M. de Morgan, at the pyramid of Dashour, has resulted in the discovery of a most important find of ancient art, including a treasure of numerous objects in gold and precious stones. This is known to every one in Cairo, and will therefore have excited the cupidity of the native burglar, who is both enterprising and daring, and, moreover, almost invariably manages to evade detection.

Hence it would be the height of imprudence to allow the collection to remain under its present conditions. The jewellery at least ought to be placed in absolute safety, for although no Egyptologist would assert that it is really the most intrinsically valuable portion of the contents of the museum, yet while it remains at Ghizeh it may lead to the destruction of the whole. Without doubt the place of greatest security in Cairo is the citadel, garrisoned by British troops, and it is there that the gold objects and jewellery should be deposited, pending the erection of a substantial and fireproof building for the museum in Cairo itself.

It must also be remembered that there is a grave source of constant danger to the collection always existing in a country like Egypt, and that has been accentuated during the last couple of years, namely, the jeopardy of an outburst of religious fanaticism, fomented by political intrigue. No one familiar with the Egypt of to-day, and acquainted with its past history, can ignore this possibility. Granted that the disturbance would be promptly quelled. But what might not happen in the meanwhile to the priceless contents of the lath and plaster palace situated a few miles outside the capital? As they stand at present, the telegraphic wire may any day startle Europe with the intelligence that the earliest records of humanity have been for ever obliterated.

THE ROMAN WALL.

THE Council of the Cumberland and Westmorland Antiquarian and Archaeological Society have recommended the expenditure of 50*l.* in making sections across the Roman wall and vallum in Cumberland, in search of the "Gromatic Ditch," whose discovery on the "Limes Rhaeticus" is exciting so much interest in Germany and also at Oxford, and in hopes of throwing some light upon the relative age of wall and vallum. The Chancellor, Mr. T. H. Hodgson, and the Rev. W. S. Calverley have been appointed a committee to endeavour to get permission to dig in suitable places and to carry out the work, in which they will be assisted by Professor Pelham and Mr. Haverfield and other Oxford scholars, who accompanied General von Sarwey along the wall last summer. It was also resolved to recommend the Society, with permission of the authorities, to deposit their archaeological library at Tullie House, where it could be made generally accessible. The meetings for the year will probably be Lake Side, Windermere, perhaps in June, and probably the Isle of Man in September.

ARCHITECTURAL ASSOCIATION SOIREE.

THE annual soirée of the Architectural Association was held on Friday evening at the Holborn Town Hall, when an operatic, melodramatic, extravaganstic trifle, as it was described, being a Lyrical Lay of Ladye Lande, in two acts, and entitled "Architopia, Unlimited," written and composed by Mr. Arthur W. Earle and Mr. E. Howley Sim, was performed by the members.

The following are the *dramatis persona* :—

ARCHITOPIANS.

THE QUEEN DIANA	...	An Aunt	...	A. W. EARLE
PRINCESS LOO	...	A pretty piece of property	...	HERBERT FORD
LETTIE (also Lottie)	}	Architesses	{	G. B. CARVILL
ARABELLA (also Pepermint)				H. PASSMORE
JABEZ	...	A bold bad Bounder	...	J. DIXON-BUTLER
LOBEN	...	An itinerant Potentate	...	C. A. FORD WHITCOMBE
MARCUS MUTTON	...	Parish Councillor	...	A. LOVEJOY
TOBIAS D. TRAPPE	...	Sanitary Surveyor	...	S. W. CURTIS

A.A. MEN.

CHARLIE	...	Algernon de Mounte Forte	...	S. CONSTANDUROS
HIGHGATE	...	An Earl	...	W. W. FURLONG
POULTREE	...	A Laird	...	A. C. BULMER BOOTH

BOYS.

NAROJI	...	Coloured	...	F. COLERIDGE SIMPSON
JEHOSOPHAT	...	An Infant	...	S. BURTON LEE

HIGHLAND WARRIORS AND DANCERS—

ALEX. FRASER and J. H. KIDD.

Stage Manager	F. T. W. MILLER
Director of Music	CLEMENT LOCKNAME

SCENE.

LADYE LANDE.

ACT I.

A SOFT AND SUNNY SEASIDE SHORE.

ACT II.

BEFORE THE GATES.

The scenery was devised and executed by Mr. E. Graham Simpson, of the firm of W. D. Simpson & Sons, St. Martin's Lane, and the various original properties provided by Messrs. Colls, of Coleman Street.

The proscenium and stage erected by Messrs. E. & A. Williams, of Southwark Park Road, S.E.

The Alexandra combination piano and organ were lent by Messrs. W. J. Ennever & Son, of Berners Street.

The extravaganza proved entertaining, and whimsical allusions were made by the actors, the majority of which referred to the Association and its present or past members. The hope was expressed that one day the President of the Royal Academy might be an architect, and "if we but had our way" paintings would have to give place to designs. Also clever parodies were introduced, particularly one "E dunno where 'e are."

Among the incidents, Charlie, Highgate and the Laird

The Earl of Highgate on the loose ;

The Laird, our Scot, who has come from the far North,

introduce themselves to Queen Diana, Princess Loo, Lettie and Arabella.

By Jove ! what jolly girls.

They eventually pair off, Charlie saying :—

Ah ! Princess Loo, the sight of you my heart has made much gayer, I'll drop the name of architect if I may be your surveyor.

In another scene Queen Diana says :—

Eh, someone another competition has just won ;

Oh, never mind the name, there's only one

Who Mounts the hills and Fords the valley deep

On the path which leads unto fame's highest steep.

All performed their parts admirably, and if we were to mention any names for special praise it would be the names of Mr. Earle and Mr. Constanduros.

The humorous parody of the A.A. official device on the programme was designed by Mr. Harold Bailey, with apologies to Mr. Walter Crane and the President.

A VISIT TO OLYMPIA.

GREECE has now, writes Mr. T. A. Fox in the *Architectural Review*, several lines of narrow-gauge railroad, which, although injurious to the primeval character of the country, have, however, the advantage of bringing within easy reach many of the interesting localities hitherto inaccessible without more or less discomfort and privation, or the expensive luxury of a dragoman and his outfit. A line has just been opened from Patras to Olympia, and it was by the unromantic conveyance of a railroad carriage that we invaded the territory of Olympian Zeus. The unobtrusive terminal station has

been kept as yet a half-mile away from the sacred precinct, as if the desecrators were unwilling to profane the holy of holies.

There is no town within nearly a mile of the site, but travellers in limited numbers are entertained at the hotel, whose accommodations for guests at the time of our visit consisted of a single room, which served in turn as sitting-room, dining-room and bedroom. A more pretentious establishment has recently opened across the way, but we were told the management was unreliable. Our hotel appeared to be the department headquarters of the army, which is used in the rural districts as police. We watched with particular interest the return of a couple of soldiers, each of whom produced from under his coat a chicken which was forthwith led to the block, and later appeared on our supper-table in a savoury stew. We suspected this delicacy was not furnished at the expense of the Government or its official representatives.

On a little knoll a few minutes' walk from the station stands the museum, a low, Classic structure built through the generosity of an Athenian banker, while in the plain beyond, watered by the Alpheios, lie the ruins of the ancient Olympia. The museum contains, with few exceptions, all the discoveries of the excavations. Foremost of them all is the Hermes of Praxiteles, one of the few originals preserved to us from antiquity. This statue is of fine Parian marble, and was found on May 11, 1877, in the Hera Temple, lying before the fragments of the base on which it once stood ; and Pausanias, that most useful Greek known to most of us only as the original Baedeker, has been the means of identifying the work beyond all question. The statue is in an exceptional state of preservation, the surface of the marble having retained its original texture, and the missing parts, which have since been restored, being comparatively unimportant. The statue enjoyed in ancient times no such high reputation as the other works of Praxiteles, but for us it is quite beyond price, and has made it possible for us to understand in some measure Praxiteles and his fame. There were, in places, slight traces of gold and colour on the statue when first discovered, but they have now almost entirely disappeared.

Every traveller in Greece is interested in trying to trace some physical similarity between the peasant of to-day and his classic ancestors. Although on the islands, notably Mitylene, I was told one often sees the fine figures and regular features of Venus and Apollo, yet on the mainland such resemblances can be seldom recognised. Now and then, however, one is startled by a pose or feature which calls to mind some Classic work.

The museum also contains the Nike of Pæonios, a wonderfully bold piece of sculpture, which represents the goddess descending to earth entirely free of support. In order to give this impression the block of marble on which the statue rests is roughly formed to represent an eagle. The figure was set on a high, slender base, the form of which was also used to give the feeling of lightness ; it was triangular in shape, so generally but one side could be seen at once, giving quite a different effect from the massiveness of a rectangular block. The celebrated sculptures from the pediments of the Temple of Zeus are well arranged on either side of the main hall, the sides being made to correspond with the width of the temple. Of architectural fragments there are few of size or special importance, but there are large numbers of lions' heads, terra-cottas, acroteria, marble tiles, &c., many of which retain their original colouring.

Descending the hill on which the museum stands, a short walk brings one to the site of the sacred precinct. The place was superficially explored by the French in 1829, who found a few reliefs, now in the Louvre. It remained, however, for the Germans, under Curtius, to thoroughly uncover the site. They commenced work in 1874, and continued for six winters. The yield of sculptures fell short of expectations, but a flood of light was shed upon the topography and architecture of the site. The most interesting remains are those of the Temple of Zeus, which stood in the midst of the enclosure and held the masterpiece of Phidias, the gold and ivory statue of the god. The bases of most of the columns are in place, and an idea of the vast scale of the structure can be had from the huge blocks of the entablature, some of which lie unbroken on the ground, and the caps of the columns, a few of which are fairly well preserved and show an echinus moulding of remarkably fine profile. The temple was built of hewn blocks of a shell conglomerate coated with stucco, which still remains in many places.

Another ruin, having a special interest for the architect, is the Heraeum, probably the oldest known temple in Greece. The forty peripteral columns, of which only six are wanting, present curious variations ; the diameters vary from 3½ to 4½ feet ; some are monoliths, while others are built up of drums. The number of flutes varies also. The most reasonable explanation of the variations is that the columns were originally of wood, and were being replaced by stone as became necessary on account of decay. Pausanias says of the temple, "Its architecture is Doric, there are pillars all around it ; the pillar in a chamber at the back of the temple is of wood." This is

certainly good evidence in support of the theory that the Doric order was developed directly from wooden construction. There is also reason for believing that part of the *cella* walls was built of sun-dried brick.

The site of most of the buildings can be identified with the map; but so little of the superstructures remain that it is almost impossible, without considerable study, to form any conception of the restored structures. Some of the pure Greek work has been supplanted by the Romans or desecrated by the cheap church architecture of the early so-called Christians, who did even more than their pagan brethren to destroy the art and architecture of ancient Greece. There are, however, many interesting architectural fragments, and on the site of the Phillipeion some fine details.

PALESTINE EXPLORATION.

ON Tuesday there was a meeting of the Palestine Exploration Fund held in the Westminster Town Hall, under the presidency of the Duke of York. A paper was read by Major C. R. Conder, R.E. He said that the interest felt in Jerusalem, as the centre of the Hebrew kingdom, made it naturally the first site to which explorers turned with increasing interest, and he believed that excavations there might still bring much to light, and that they were still possible, though there were many difficulties in the way. It was an inhabited city, and it contained one of the most sacred places of the Moslems. The southern hills outside the city walls were allowed by all to have been included in the ancient city before the Captivity. The western hill, usually called Sion, was that of the upper city of David and Solomon, and the south-west angle of its fortress-wall had been discovered. It only required to be traced towards the east. The little spur above Siloam was the quarter where the priests' houses grew up south of the Temple, where the kings of Judah had a palace, and where some of them were buried in the royal garden. It was walled in by the later kings, and the wall was rebuilt by Nehemiah. There also, therefore, they had much reason to hope for important discoveries. They might light on the palace itself and might find some remains of early archives on its site. The site of Herodium, the burial-place of Herod the Great, and the rock-cut tomb supposed to be that of the Patriarchs, under the sanctuary of Hebron, were also important objects for future investigation, and there were several uninhabited places which would yield a rich harvest to the explorer. Generally speaking, he thought it was along the great trade routes of Palestine that the most important sites occurred. The towns in the mountains were for the most part small, and the civilisation of early ages was chiefly found in the plains, along the great highways from the Euphrates, and from the sea to Damascus and to Egypt. There was, he thought, some evidence that in the earliest times the great centre of native civilisation was in Lebanon and not in Southern Palestine. Many important remains had already been found in this that region, which was full of deserted mounds some 40 feet high, which concealed unknown treasures of antiquity. The sites in region which required exploration, and which others would soon explore if we did not, included especially Kadesh itself, Orpad and Karchemish. The Society should not confine itself between the limits of Beersheba and Dan, for the kingdom of Solomon reached the Euphrates; and the "Land of the Hittites" was quite as important for Bible study as Southern Palestine. Their limits should be drawn from the Egyptian boundary to the foot of the Taurus, and the most promising sites to be found in the plain of the Orontes east of Lebanon. In Lebanon itself inscriptions of Nebuchadnezzar were cut upon the rocks; and the Assyrian conquerors, returning from their expeditions to Egypt, left monuments at Beirut and at Samala describing their distant victories. The Egyptians set up statues near Orpad, and it was quite possible that in that region they might yet recover texts which would tell of the conquest of Jerusalem by the northern enemy, or early inscriptions even of the time of Solomon. To illustrate this subject he called attention to what had actually been discovered quite recently by German explorers at Samala, in the extreme north of Syria, and to the importance of their explorations as connected with the Bible history. These results were as yet very little known in England; but the statues which they had brought home were among the chief treasures of the Imperial Museum in Berlin. There was no doubt that this important field would be further worked by German scholars, and George Smith long ago called attention to its interest and value. It was to be hoped that we might yet find Englishmen co-operating with the Germans in the recovery of its treasures. Samala lay east of Issus and south-west of Merash, where several very important Hittite inscriptions had been found. But the antiquities of Samala were not Hittite, but represented the civilisation of the Syrian race, which worshipped Hadad, the god of Damascus, and which used the Phœnician alphabet almost as early as the time of the

Moabite stone. A circular enclosure, some 800 yards in diameter, with three gates, here enclosed an acropolis on a hillock in the plain. The great south gateway of the acropolis was built apparently about 730 B.C., and adorned with forty bas-reliefs cut in hard basalt, in a rude imitation of the Assyrian style. Men with captives, a bowman, a horseman, and a soldier with an axe were represented with bulls, deer and lions; also mythological figures—a lion-headed man, a winged lion ramping and a sphinx. A statue close by had a Phœnician text of thirty-four lines in relief. It represented the head and body of a gigantic bearded figure with a round cap, and the inscription was on the columnar pedestal. He had not seen any translation of this text as a whole, but it was of much value as showing the beliefs of the Syrians about 800 B.C. Touching the bearing of Palestine exploration on the study of the New Testament, they might look, the lecturer said, to valuable results in this respect, and some had indeed been already obtained. Much that was of interest regarding the early history of Christianity in the East in the second and third centuries had also been brought to light, and more remained no doubt to be found, especially at Cæsarea and at Ascalon. In conclusion, he said that much remained to be worked out, and they must be up and doing. Twenty years ago the Palestine Exploration Fund stood almost alone. Schliemann's work was only beginning to be noticed, and many important Egyptian discoveries were still in the future. But now the movement had spread in every direction. The French and the Germans were busy in Greece and in Syria; the Egyptologists had added immense stores of valuable material to our collections. The members of the Palestine Exploration Fund must not allow others to outstrip them, or neglect one of the most hopeful and important fields of research.

CHESTER CASTLE.

AFTER many months of wearisome negotiation and tantalising red tape, it has at length been definitely arranged, says the *Chester Chronicle*, that the Chester Castle Prison shall be reconveyed to the county, the amount which the County Council are called upon to pay for such reconveyance being 4,734*l*. This is good news for the county authorities, and, as it will lead to some extensive and much-needed alterations of the court arrangements, as well as to the provision of several county offices in one building, everybody who has business at assizes or quarter sessions, or who takes an interest in county government in Cheshire, will be pleased that the reconveyance has been at length effected. For years now the prison has been utilised solely for military offenders, but for a long period it was a common gaol, and it is interesting to recall now what Pennant had to say of it in 1777, as quoted in Hemingway's "History of Chester":—"The county gaol for felons and debtors is the last place to be described. I can do little more than confirm the account of it by the humane Howard. Their day confinement is in a little yard, surrounded on all sides by lofty buildings, impervious to the air except from above, and even unvisited by the purifying rays of the sun. Their nocturnal apartments are in cells 7½ feet by 3½ feet, ranged on one side of a subterranean dungeon, in each of which are often lodged three or four persons. The whole is rendered more (wholesomely) horrible by being pitched over three or four times in the year. The scanty air of this strait prison yard has to travel through three passages to arrive at them—through the window of an adjacent room, through a grate in the floor of the said room into the dungeon, and finally from the dungeon through a little grate above the door of each of their kennels. In such places as these are the innocent and the guilty permitted to be lodged till the law decides their fate. Mr. Howard compares the place to the Dark Hole of Calcutta. The view I had of it assisted to raise the idea of a much worse prison, where

No light, but rather darkness visible,
Served only to discover sights of woe."

Such was the castle of Chester as described by Mr. Pennant in the year 1777. Since that period (says Hemingway) "the upper ward has experienced little alteration, excepting repairs and the demolition of its gateway with its towers. The lower ward, however, has been entirely demolished, and a series of buildings erected under the direction and from the designs of the late Mr. Harrison, which may well be classed among the most magnificent buildings of the kind which the kingdom can boast. The expenses incurred by these erections have been defrayed by the county rates, aided by the revenues of the river Weaver and by the contributions from the national purse towards the parts used by Government as an armoury and barracks."

It is contemplated, we gather from the proceedings of the standing joint committee, after the alterations alluded to have been carried out, to sell or lease to the War Office such part of the present prison as will not be required for the purposes of the alterations, so that part of the premises will still be

used as a military prison. Mr. Stanhope Bull, the county surveyor, estimates that the whole of the contemplated improvements can be carried out for 6,330*l.*, 4,900*l.* being apportioned to the alterations in the Crown Court, and 1,430*l.* to the provision of offices for the county surveyor, county auditor, Government auditor, and so on. Before indicating the exact nature of the alterations, we may here quote again from Hemingway, who gives what will be recognised on the whole as an accurate description of the Crown Court and the entrance thereto—"the magnificent hall of justice," as he calls it. "Before the latter," he says, speaking of that court, "is a portico with twelve stupendous pillars in double rows, each of which is 22 feet in height and 3 feet 1½ inch in diameter, hewn out of a single stone from the Manley quarry. The ceiling, roof and covering are constructed of the same stone, no timber being used throughout the whole. The hall itself is of a semicircular form, 80 feet in diameter, 44 feet high, and, including the recess for the judges, 50 feet in width. Round the extreme part of the semicircle is a colonnade of twelve Ionic columns, each of a single stone, 22 feet high, supporting a semi-dome divided into large deep caissons or coffers; in the centre of each is an ornamented rose, which, opening to the roof, serves the useful purpose of ventilating the whole of the court to any degree requisite. The bench of the chief justice is in the centre of the large recess; the seats for the grand and petty juries on the right and left; the counsellors' seats are a little lower; the prisoner's box is on the same level, from whence there is a commodious passage under the hall to the gaol, by which means there is no noise or confusion in the bringing to or removing prisoners from the court; from the prisoner's box is a gradual and regular elevation by circular steps through the whole court to the base of the Ionic pillars which form the colonnade. By this plan upwards of a thousand spectators may have a perfect view of the court, prisoners and witnesses. From its simple form and chaste style of architecture, showed to the best advantage by being lighted from above, this hall has an imposing effect upon the spectator, and gives a proper dignity to the seat of justice." So much of the proposed alterations as have already been decided upon will involve the removal of "the bench of the chief justice" from its present position to the opposite side of the Crown Court. The large pillars alluded to in the foregoing extract will not be interfered with, but the removal of the judges' bench enables Mr. Bull to provide for some improved accommodation, which is sure to be appreciated. In the first place the judges' retiring-room, in place of the present shabby apartment, will be far more ample and better appointed. Then the rooms for witnesses and jurymen will be much better than the existing ones, and other provisions for the convenience of those who have business at the court will be made which have hitherto been found impracticable. If the County Council sanction the expenditure of 1,430*l.* mentioned above, there will be an office for the county surveyor, another for the county auditor, a room for the Government audit and living and sleeping apartments for the hall-keeper, who now resides away from the premises. Altogether the improvements will tend to the convenience of a large number of people, and the county will have no need to grudge the modest expenditure foreshadowed in Mr. Bull's estimate.

THE WEST RIDING COUNTY COUNCIL OFFICES.

REVISED estimates for the new county offices of the West Riding County Council, at Wakefield, have been prepared. The estimates previously approved amount to 68,824*l.*, less 400*l.* for materials on site. The new estimates are as follows:—Tender (including fees of quantity surveyor), 76,824*l.*; boiler (additional), 500*l.*; architect's fees, 3,200*l.*; clerk of works, 750*l.*; total, 81,274*l.*, or 12,850*l.* in excess of the former estimates. The general purposes committee, in their report, deal at length with the question of the erection of offices, which had been referred back to them for consideration. Alluding to the question whether the offices shall be built at Leeds or Wakefield, the committee say the increased cost of providing offices at Leeds arises mainly under the following heads:—(1) Purchase-money of site; (2) the cost of buying a site and erecting premises for the police headquarters; (3) some extra cost for building at Leeds instead of Wakefield, though this is a relatively small item. In their former report the committee mentioned two sites in Leeds as being suitable, and these, the committee believe, are still available, subject to existing tenancies, namely, a freehold site having frontages to Park Place, Queen Street, and York Place, Leeds, containing 4,630 yards or thereabouts. The other site is known as the Leeds Cloth Hall site, bounded by King Street on the west, Quebec Street on the north and a side street on the east, and containing 4,124 yards or thereabouts. It was stated that either of these sites would be sufficient for the accommodation of the County Council and its offices, but excluding any provision

for the West Riding constabulary and the Registry of Deeds. Of these sites, the second is clearly far preferable. In view, however, of the rapid growth of the county business, and having regard to the area necessarily occupied by the buildings, it is necessary to bear in mind that the Cloth Hall site is 745 square yards smaller than the Wakefield site, and that the absence of a frontage on one side further reduces its capacity for building purposes, so that little or no margin would remain for future extensions. A further consideration is the fact that in view of the decision of the County Council additional outlay has been incurred on the police headquarters at Wakefield. Further extension has taken place in the force, and, in particular, provision has been made for a small force of mounted men, for whom stabling and barracks are being provided. Consequently, the cost of removing the police headquarters to Leeds would be to that extent increased, and the objection which has been raised to locating the police in so large a town as Leeds would be to some extent emphasised. The reasons, therefore, for selecting Wakefield in preference to Leeds are stronger now than when the committee last reported on the subject. The committee next deal with the question of the excess of the amount of the tender over the estimate approved by the County Council, and say that after very full and careful consideration they have come to an almost unanimous conclusion that to carry out any considerable portion of the reductions which have been suggested would entail the virtual destruction of the architectural character, and would result in the erection of a building which could not be considered satisfactory, having regard to the purposes it is to fulfil. They consider that the only reductions which it is desirable to make are the modification of the caretaker's quarters, and the omission of the electric generating plant, amounting together to 3,560*l.* These items being deducted, Messrs. Armitage & Hodgson's tender amounts to the sum of 76,824*l.*, including a sum of 1,030*l.* for the quantity surveyor's fee and cost of lithographing the bills of quantities.

The chairman of the committee (Colonel Mackie) moved on Wednesday that the decision of the County Council to provide offices at Wakefield be adhered to, and that the tender of Messrs. Armitage & Hodgson, contractors, Camp Road, Leeds, amounting to 76,824*l.*, be accepted.

GENERAL.

The Competition for the French postage-stamps has produced about six hundred designs. On some the effigy of Joan of Arc is substituted for the usual figure of the Republic.

Conferences between the Technical Education Board and representatives of London industries will be held at the County Hall, Spring Gardens, during June and July. The first meeting will be devoted to the building and furniture trades.

The Loan Exhibition in the Corporation Art Gallery has already attracted over 130,000 visitors.

A Reredos in teak wood, designed by Mr. Pearson, R.A., has been set up in the church of St. Helen's, Bishopsgate.

M. Jan Van Beers has been awarded the principal gold medal by the jury of the Vienna exhibition for his portrait of M. Henri Rochefort.

The Emperor of Germany has subscribed 1,000 marks towards the memorial of Dr. Schliemann, which is to be erected in Lübeck.

The Annual Dinner of the Surveyors' Institution will take place at the Holborn Restaurant (Venetian Room) on Monday, 28th inst.

The New Baths in Kirkstall Road, Leeds, are to be proceeded with at once, and the contracts signed for the proposed baths in Union Street.

The Eccles Town Council have decided to build an infectious hospital to contain twenty beds, at an estimated cost of between 4,000*l.* and 5,000*l.*

The Estates Committee of the Oxford City Council have recommended the appointment of Mr. W. H. Castle, of Oxford, to the post of estates surveyor. Seventeen applications were received for the appointment.

The Site for the proposed new post-office at Bury is still unsettled. The postal authorities prefer a site in Silver Street that will cost 120*l.* per annum, while the Town Council prefer a site in Manchester Road at 40*l.* per annum. It has been decided to again approach the authorities to get their consent to adopt the latter site.

A New Massive Oak Reredos has just been placed in the chancel of Braintree parish church, Essex, as the result of a legacy from the late Miss Wakeham. The architect was Mr. Walter E. Hewitt, A.R.I.B.A., of 7 Great College Street, Westminster, and the work has been ably carried out by Mr. Parmenter, of Braintree, and forms a very pleasing addition to the old church, with which it harmonises very well.

The Architect.

THE WEEK.

THE application for advice which was submitted to the magistrate at the Lambeth Police Court on Tuesday by the clerk of the Camberwell Vestry is a comment on the incompetency of English officialdom. County Courts are public buildings, and as such they ought to be models of sanitation. It appears, however, that when one of the vestry's inspectors visited the Lambeth County Court and tested the drains, he found the place in a most abominable state. The inspector served the usual notice, but the authorities, while promising to do the work, took the objection that the court was a public building, and refused to admit the officers of the vestry or to give them any information. As the vestry clerk could find no clause in the Public Health Act exempting public buildings, he asked the magistrate for an order for the inspection of the premises. The magistrate said he did not think he could render the vestry any assistance at present. The neglect of the authorities is not confined to Lambeth. Throughout the country complaints are heard about the state of court-houses and other public buildings. In the majority of cases the evils arise from the defective planning, and it would be expensive to remedy them. Besides, alterations might lead to inquiries which officialdom could not sustain. It is therefore politic to keep the doors closed against inspectors and to assert the privilege of exemption from examination.

THE Association for Promotion of the Fine Arts in Scotland was one of the most successful of the art unions. A society that gave from 500*l.* to 250*l.* for single historical and figure pictures, and commissioned engravings like MILLER'S *Kilchurn Castle*, after TURNER, in its early days some fifty years ago, was a benefit to Scotland. That the plates issued were Scottish in subject was also an advantage, for the support was thus applied to further a definite purpose. The Association having ceased to exist, no time has been lost in arranging a successor to it. The "New Art Union for Scotland," for that is the title, is to serve a similar purpose, but the rate of subscription will be lower than in the Association. Sir GEORGE REID, the late president of the Scottish Academy, in a letter to the Secretary writes:—"A Scottish Art Union established on the lines you propose, with a moderate annual subscription, and allowing prize-winners to select the prizes themselves in any of the annual picture exhibitions, should have a fair chance of success, if carefully and economically managed. The Royal Association for the Promotion of Fine Arts in Scotland did an immense amount of good during the fifty or sixty years of its existence. Now that it has ceased to be, there is a good opportunity for starting a new association to take its place, but perhaps on somewhat different lines. At present, owing to the long-continued depression, artists as a class are suffering not a little. An association such as you propose might help to lessen the evil by encouraging the purchase of works of art in our annual exhibitions. I think it is well worth trying. I wish you all success."

THE part of the Transactions of the Edinburgh Architectural Association which was sent out this week contains reports of some interesting papers, including Mr. AITKEN'S on "Old Edinburgh" and "Modern Edinburgh," Mr. W. W. ROBERTSON'S on "Holyrood Abbey and Palace," and Mr. J. M. GRAY'S on "Metal Engraving." The first named has necessarily many references to northern architects. It appears that the laying out of the New Town was made a subject for competition. The plan by JAMES CRAIG was adopted in 1767, and he laid the foundation-stone of the first house in Rose Court, George Street. The man who had the courage to "feu" the plot was a mercer named NEALE, and he was presented with 20*l.* by the magistrates, and it was declared that the plot was to be for ever exempt from burghal taxes. CRAIG received a gold medal and a silver box with a certificate of the freedom of the city in it. More important was "a large and lucrative practice in designing the various buildings which were erected in the carrying out of his feuing plan." His success inspired him with a desire to alter the Old Town. The Calton Hill

approach is to be credited to DAVID STEVENSON, of Bell Rock fame, and he contemplated the erection of three terraces of fine houses around the hill, but his scheme was never realised. THOMAS HAMILTON and W. H. PLAYFAIR were agents in imparting the character to Edinburgh which all the world admires. HAMILTON designed the High School, the College of Physicians, the Burns Monument on Calton Hill. He was one of the founders of the Scottish Academy, but when the galleries were to be erected the commission was given to PLAYFAIR, who was a native of London. However, he had migrated to Edinburgh when he was a boy, and was taught the art by WILLIAM STARK, a man much respected by Sir WALTER SCOTT, who said that more genius died with STARK "than is left behind among the collected universality of Scottish architects." PLAYFAIR appears to have designed more buildings in Edinburgh than HAMILTON. His best work is supposed to be the Royal Institution. He was to have charge of the reproduction of the Parthenon as a national memorial of the war with France, for which Professor COCKERELL prepared the plans, but no more than a part was erected. It may not be known to many in the South that A. W. PUGIN aided in the production of the Gothic Assembly Hall. We trust Mr. AITKEN will not be contented with the instalments of the architectural history of Edinburgh he has given, for there is much else in the romantic town which is worth the attention of so earnest an investigator.

A COMMITTEE has been formed in Pérouse, with Professor BELLUCCI as president, for the purpose of erecting in the town a memorial of PIETRO VANUCCI, better known as PERUGINO, the painter. The professor has requested the Académie des Beaux-Arts to appoint a similar committee, in order to raise subscriptions in France. It would be contrary to the regulations of the Académie to undertake a financial operation of that kind, but M. DAUMET, the president, asked the members to subscribe in their individual capacity. It is becoming on the part of the people of Pérouse to be proud of the connection of the painter with their town. They cannot, however, claim him as a native. PIETRO was born in Citta della Pieve, which is twenty miles distant from Perugia, and hence he sometimes signed his name as "PIETRO DE CASTRO PLEBIS." The humble house in which he was born in 1446 was standing until 1829, when it was demolished to make room for the enlargement of an adjoining house. Opposite was the Chiesarella, which contained PERUGINO'S fresco *The Nativity*, one of his most characteristic works.

ALTHOUGH six hundred designs were sent in for the contemplated French postage stamp, the jury could not discover one which they considered to be worthy of recommendation for adoption. The result may not appear creditable to French designers, but it must be remembered that something more than a mere portrait was sought after. The figures must be symbolic of Republican France, commerce, letters, and the end of the century. It was anticipated that several single figures, which would be suited for adaptation as statues or medals, were certain to be produced. The failure in Paris will not appear discreditable to anyone who is acquainted with the history of the "Mulready envelope" and other attempts to obtain an expressive stamp in England.

ONE of the treasures of the Bodleian Library, at least for Scotsmen, is the Gospel Book of S. MARGARET, the wife of MALCOLM CANMORE. Among all the Mediæval women there was no finer representative of femininity, and the influence she exercised on the wild tribes of the North cannot be matched by any heroine in a fairy tale. Architecture owes much to her, for she realised the advantages of beautiful buildings as civilising agents. The Gospel Book is a selection of the parts employed in the liturgies, and the illumination is an excellent example of early eleventh-century work. We believe the Marquis of BUTE, who has already rendered invaluable services to archæology, is about to add another by having a facsimile of the manuscript prepared. The book itself has a history, and owes its preservation to a series of fortunate circumstances. It is only right that the world should become better acquainted with its history and style.

CANALETTO.*

AMONG all the painters not one has shown so much respect for architecture as ANTONIO CANAL. Buildings were made the subjects of pictures before and since he appeared, but, as a rule, the artists were afraid to depend for interest on the character of the details. The preference for ruins indicates that painters believed what has been called the pathetic fallacy is influential in the painting of architectural subjects as in poetry. When SCOTT, for example, advised people to visit Melrose Abbey by moonlight if they wished to see it at its best, he was merely suggesting a favourite practice with painters. CANALETTO was not a sentimentalist of that class. He believed that buildings, especially those in his native place with which he was most familiar, were beautiful objects, and could not be too faithfully depicted. He did not consider it was an advantage to conceal details by deep shadows, or to scamp the representation of them through a fear that he would be charged with monotony. He was loyal and reverential towards architecture; he was an honest man, and therefore he tried to be as faithful to the reality as his colours and pencils would allow. Mr. RUSKIN, who commonly is satisfied with concentrating his keen vision on a bit of sculptured ornament or other part of a building, and endeavours to make a world out of it, is dissatisfied with the prosaic treatment of CANALETTO's pictures; artists of our time who fondly believe that if details are shirked, breadth is sure to be gained, look down on him because he was not imaginative. The fact is overlooked that CANALETTO could have produced his views with far less labour if he adopted a different manner. He lingered over a multiplicity of details because he found as much satisfaction in representing them as another artist finds in painting leaves. He is entitled to employ his own manner of expression, and architects at least should not be found among those who undervalue his works. No less remarkable than his loyalty was his impartiality. COINDET says that he preferred the works of PALLADIO, which had for him "un attrait tout particulier." He could not suggest the characteristics of Venice unless he made one or other variety of Renaissance prominent in the majority of scenes. But whenever a Gothic building appears in a view, CANALETTO never fails to do it justice.

We believe that many of the aspersions of which he is and has been the victim arise from what may be termed the chronological prejudice. As at one time it was asked, "Can any good come out of Nazareth?" so most of the criticism against CANALETTO becomes irrefragable if it be inquired, "Could a man be an artist who lived in the dullest of all periods—that is, between 1697 and 1768, or thereabouts?" The Renaissance in Italy was then at its lowest level, and as ANTONIO CANAL's name must appear in the histories among the last generation of the decadents, it is assumed that he was a sort of notorious representative of those who had an alacrity in sinking. Probably it was with the hope of gaining some consideration for him that FRANZ KUGLER united IL CANALETTO's name with those of his contemporaries, JOSEPH VERNET and THOMAS GAINSBOROUGH, as if he deserved to be classed with the pioneers of a new age rather than to be identified with the expiring conservatism of the first half of the eighteenth century. For the sake of his reputation it would have been an advantage for CANALETTO if he had been born a century or more earlier.

In a different age he might also have found a biographer. One of the remarkable circumstances connected with CANALETTO is the darkness which surrounds him. He was apparently a prized celebrity in Venice, for he was always setting up his easel in the public places, and patrons of art would be glad to be escorted by him through the byways and waterways of the city. But of the artist's daily life little is to be discovered. M. ADRIEN MOUREAU, the latest biographer, does not therefore attempt, like some writers, to delude his readers, for he acts as if he believed an artist's life is expressed in his works, and he devotes his pages to an investigation of CANALETTO's paintings and their relation to the time when they were produced. The obscurity is the more tantalising, because CANALETTO prepared a memoir of himself and a genealogy of his family, which he believed to be patrician.

At the time of ANTONIO's birth, on October 18, 1697, his father, BERNARDO CANAL, was one of the scene-painters of Venice, and was not the most prosperous among them. The boy helped in decoration as soon as he was able, and in that way acquired the skill in the production of effects which is so decisive it is supposed by some to be a sort of trick. Young CANALETTO was not destined to remain long in theatres. He relates how, for some reason which is not told, he excommunicated the stage and turned his steps towards Rome in his twenty-second year. An artist with an architectural bent could not fail to be impressed by the remains, and CANALETTO spent his days in drawing ancient buildings, and plates from some of them were etched by an artist who was, it is supposed, an Englishman. In Rome he was excelled by PANINI, who was not satisfied with representing buildings as they existed, and accordingly he returned to Venice. With the exception of a couple of visits to London, one of which was prolonged for two years, and occasional trips to Verona or Padua, CANALETTO appears to have spent his life in his native city.

There were two painters in vogue when he returned to Venice, but in a competition CANALETTO was preferred, and ever afterwards his position was unassailed. The English consul SMITH was one of the earliest to perceive the artist's genius and to profit by it. He posed as a patron of the arts, but he was one of that class of dealers who are the most exorbitant, for he charged for the sacrifice he underwent in parting with a treasure. By the consul's diplomacy CANALETTO became a favourite in England. Probably there are more of his works in this country at the present time than in Italy. The artist was shrewd enough to perceive it was wiser for him to deal direct with Englishmen, and he was so well received in London he was not unlikely to have remained, but the climate overcame him. The reputation he possessed among artists is evident from occasional references to him. For instance, we find BARRY in one of his Academy lectures saying that the street views of London could be made interesting if there was a CANALETTO to paint them. He produced some English views which must excite regret there are not more of them, for his pencil was as trustworthy as any photographer's lens.

London, however, has been transformed, and the tests of his accuracy are not forthcoming. Venice in its most important features is still the same. There are some visitors, especially those whose residence is brief, who say that CANALETTO has not realised the spirit of the place. They should remember that the appearance of Venice often corresponds with the moods of the stranger. A man who has stored his mind with the real and imaginary events which are associated with the buildings will find that the dreariest day corresponds with something which memory can call up. If he is able to create ghosts, there is no more fitting scene for their display. The shopkeepers, hotel-keepers, the agents for letting out historical chambers as lodgings, the guides, the boatmen, the Customs' officers, and, in fact, the whole of the population who live on the spoils of strangers, look on everything ancient in a different light. When Venice was a great trading city, native and foreign merchants were likely to have taken a similar view. On bright days they saw buildings so clearly that every tile was visible, they witnessed fêtes which were not to be paralleled elsewhere, they were jostled in crowds which contained men from many regions. But Venetians and strangers could not forget that everywhere individuality asserted itself. The terrible councillors, podestas, procuratori, bravi, could not enforce building regulations like those which prevail in little towns in England. Every architect appeared to have had the privilege of doing anything which was desirable to himself or his clients. At the great festivals the people were allowed to enjoy themselves in their own way. The canal police were indifferent to the advantages of keeping gondolas in lines and other means of regulating traffic. In the public places there was no apparent control. All this liberty is suggested by CANALETTO, but people are dissatisfied with it when it appears in a picture. They prefer to see all figures inspired by one object. They can admire TURNER's "Sun of Venice," appearing as if the sails were clothed in celestial light and attracting all eyes; but the old "Bucentaur," as CANALETTO represents it, a sort of "Maria Wood" on a colossal scale, which by those who had not the privilege of admission was likely to be treated as a nuisance,

* *Les Artistes Célèbres: Antonio Canal, dit le Canaletto.* Par Adrien Moureau. Paris: Librairie de l'Art.

does not seem to be shown in its poetic aspect. St. Mark's also may be considered as not having its due because the artist introduced an open-air theatre near it, and placed booths close to the principal entrance. By this treatment the peculiarities of Venetian thought are suggested, and it becomes evident that the pomp of the doges and council had also its humorous side.

M. MOUREAU takes CANALETTO's pictures and etchings as texts, and explains how far they correspond with Venetian life as described by travellers and letter-writers. His chapters on Venetian society in the eighteenth century, and the subjects of the pictures, form a commentary on the artist's principles which is invaluable. Any one who visits Venice will find a new interest in the scenes from what is written by M. MOUREAU. He also criticises CANALETTO's manner as a painter and etcher with sound judgment. Then there is a chapter on pupils and imitators of ANTONIO CANALETTO, which forms a necessary development of the subject. The numerous illustrations are on a large scale, and they are among the most successful of modern reproductions. To architects especially the latest addition to the "Artistes Célèbres" appeals as a memorial of the great man who served their art with all his powers.

ARCHITECTURE AT THE ROYAL ACADEMY.

IN addition to the residences, schools, &c., already noticed, some more examples of secular buildings deserve to be mentioned. Mr. WATERHOUSE is represented by the Prudential Assurance Buildings, Nottingham. The site is more favourable for display than the majority of those selected by the company in provincial towns, and accordingly, while the building is in red brick and terracotta, it does not recall the head office so readily as some others. The tower is a gain to the neighbourhood. Another building on a corner site is Mr. DOLL's Premises for the Association for the Blind in Tottenham Court Road, which is rather showy, although not likely to have been expensive. The Residence at Monaco by Mr. JOHN GILES is of unquestionable modern Italian, and the rows of statues break the monotony of the long horizontal lines. The London and South-Western Bank, Holloway, by Messrs. TRUEFITT & WATSON, reveals what can be done with a limited site, without having recourse to the pretentious commonplaceness which some banking companies prefer for their branches, although they are aware it exemplifies jerry-building in its worst or most ambitious stage. The pavilions of the English Mission Hospital, Jerusalem, are arranged by Mr. BERESFORD PITE around the arc of a semicircle, and are in keeping with the place. Mr. BELCHER sends additional drawings of the Institute of Chartered Accountants, and a new water-colour of his design for completing the South Kensington Museum. The drawing of the principal entrance of the Northampton Institute, Clerkenwell, expresses the general boldness of the design, as it shows windows and tower as well as doorway. The theatre in the New Cross Road, by Mr. W. M. BRUTTON, is a departure from the stereotyped building. Red brick and terracotta are used, there are real windows, and other signs that it is a habitation and not a shell. Mr. A. KOCH's General Post Office, Zurich, is Anglo-Dutch in character, and more pleasing than other buildings exhibited formerly by him. The Pathological Buildings, Glasgow, by Messrs. BURNET, SON & CAMPBELL, are picturesquely grouped, but might be taken for an ecclesiastical college. Messrs. CHARLES SMITH & SON, in their Street Corner in Wokingham, exemplify what is being done by some architects to preserve a provincial character in the additions to towns, and which is preferable to foreign importations.

If a stranger visited the Architectural Room during any of the exhibitions he must be surprised at the number of new churches which appear. On the Continent there is no evidence of a similar increase. This year the average quantity has been exceeded. It is evident, however, that in the majority of them economy was very carefully studied, for apparently the desire of clergy and committees was to provide space for a multitude at a cheap rate, and there are some interesting experiments to attain that end. One is the church at Portsmouth for the Winchester College Mission, which is of the basilican type, and somehow has a

hospitable look. The painted decorations would enhance its interest. Another example is the Labour Church, by Mr. G. L. MORRIS, which has a wide nave, but the pair of towers are not a necessity. In Mr. ASTON WEBB's chancel of St. George's Church, Worcester, there appears to be an absence of the dim religious light of the old days, and the figure decorations would be pleasing to the eye. But one of the potters or ironworkers would be likely to interpret the massive railing on a masonry base which separates chancel from nave as provided to keep men of his class at a distance. According to KEELE, after a sound rule of faith, nothing is of so much consequence as a sober standard of feeling in religious matters, but some men seem brought by their feelings to the belief that a chancel should be fortified by iron and masonry until it becomes almost invisible. In gratifying their imagination they forget that they cause weaker brethren to imagine a connection between chancel and communion. The two drawings of St. Saviour's Church, Southwark, show respect for the style of the older parts. Mr. BODLEY contributes two designs. The church at Eccleston secures attention by its low but picturesque tower, and especially by the flying buttresses. Such are not often seen of late in the Academy. The church for the Society of St. John, at Cowley, in addition to a low crenellated tower, has a square buttress or pier at the end, on which is a relief of the Crucifixion. Mr. J. NEALE, in the new nave of St. Peter's, Bushey Heath, employs circular openings within recessed arches in the nave. A memorial pulpit in the same church is adorned by figures on a large scale and by a band of vigorous ornament. Messrs. BROOKS & SON's church of the Good Shepherd, Gospel Oak, is shown on two geometrical drawings, and like many of their later works it has no tower. The treatment is simple but massive. In the baptistery at St. Peter's, London Docks, Mr. M. B. ADAMS has introduced a gallery approached by steps, as the area to be treated is very restricted. The font obtains the importance that should belong to it, and in designing the elaborate ironwork the nature of the material has been respected. What might easily appear as an uninteresting corner has gained character and claims consideration as a complete work. In the church of St. Thomas, Wandsworth, Mr. E. GOLDIE has endeavoured to get over the objection to massive piers which worshippers in aisles usually entertain by diminishing the diameter of his piers to a minimum. As the nave is high there may be a little risk, but the effect is not satisfactory, and will help those who wish to see aisles abolished in churches where the worshippers are imagined to be on an equality. The Moorland Church, by Mr. B. F. FLETCHER, is probably only a design, but it is interesting, as it provides "Sunday school and shelter for horses and carriages of distant parishioners." Mr. GRAHAM FAIRLEY's Village Church, Broxburn, is a good type of the simple village church which need not impose heavy obligations on poor congregations in Scotland. Mr. BELCHER's new stalls and decoration of church, Pye Street, Westminster, will astonish the people of the neighbourhood by the costly carving and colour decoration. Outlay of that sort is often more attractive than eloquence, and especially in slums. The new front, St. Philip's, Clerkenwell, by Mr. H. D. WILKINSON, complies with requirements; for the space is divided between a tower and a window, although it would barely suffice for either alone. The church of St. Clement, Bradford, stands on a slope, and Mr. E. P. WARREN has therefore placed a terrace outside approached by steps, which enhances the interest of the building. In the church of St. Bartholomew, Ipswich, Mr. SPOONER proposes to use a series of pictorial panels under the springing of the roof, which will form a frieze. The depth is inadequate for effect. The Congregational Church, West Hampstead, by Messrs. SPALDING & CROSS, appears to be arranged differently from the majority of churches in order to suit the services. The design for St. Aidan's Church, Walton-le-Dale, represents a building that is a model of an English country church in its grace and quietude. Mr. W. G. ROWAN has in the Cathcart United Presbyterian Church, near Glasgow, produced one of the most interesting churches in a district where there are many rivals, but a tower and spire would appear to be a necessity.

There are several designs for stained-glass, prominent among them being one for the Fitzalan Chapel, Arundel,

by Messrs. JOHN HARDMAN & CO. Mr. A. GWATKIN has another frieze, in which plant form on an immense scale is employed. Mr. J. S. BABE'S "Pros Olympon" is a frieze in which the gods and goddesses are arranged in parallel lines at an angle, like the strokes in a copybook. It is not easy to represent human forms in flight, the most successful attempt being GEORGE CRUIKSHANKS'S version of traffic across the Straits of Dover, but the diversity he was able to employ would be considered as unbecoming in decorative work. PRELLER, in his great frieze that was derived from the "Odyssey," has, however, contrived to avoid monotony in dealing with the flights of the immortals. The design for a semicircular corridor ceiling, by Mr. G. C. HORSLEY, consists of trelliswork varied by panels with figures. Mr. H. WILSON'S study for reredos in Holy Trinity Church, Chelsea, is as gorgeous as a combination of mosaic, colour and metalwork, supplemented by stained-glass, can produce. Another large drawing is a portion of a banquet hall in Renaissance style by Mr. W. F. RANDALL. Mr. CLEMENT HEATON has skilfully combined coats-of-arms to form a part of the decoration of the Imperial Institute. Mr. W. G. B. LEWIS has a decoration for a dining-room in which light brown is the dominant colour. The cartoon for altar-piece, by Mr. G. W. RHIND, the subject being the Crucifixion, may be taken as an original version. The cross is of great height, and CHRIST is seen surrounded by angels while below are draped figures of the three Marys.

Antiquity has not many representatives this year. Mr. W. H. BREWER'S vigorous drawing of a high altar in Moosburg is the most prominent example. Mr. A. C. BLOMFIELD has a drawing of a part of the mosaic pavement in St. Mark's, Venice. Mr. WILLIAM THOMSON'S old gateway at San Remo is a successful example of the modern method of emphasising effects of light and shade, to which drawings in ink are so well adapted. One of GRINLING GIBBONS'S doorways with a quaint broken pediment is the subject of a drawing by Mr. A. H. BELCHER. Mr. PHENÉ SPIERS'S practised hand has rarely been more successful than in his views of the interior of the original mosque at Damascus, which was, we believe, erected for another creed.

The Architectural Room corresponds in character with the galleries of paintings. This is not a year for new buildings of exceptional importance, but an unusual number of architects have produced designs which are considered worthy of exhibition. It is a misfortune that few people will take the trouble to glance at the drawings on the walls, and it will still be believed that English architecture is far behind sculpture and painting.

SHEFFIELD SOCIETY OF ARCHITECTS.

AT the annual meeting of the Sheffield Society of Architects and Surveyors just held, Mr. E. M. Gibbs, the president, presided, and there was a good attendance of members.

The Hon. Secretary read his annual report, which was adopted after some discussion. Mr. Gibbs remarked in moving the adoption that there was a good field of work for the new Council to take in hand, and he thought that more might be done in the future than had been attempted in the past if the younger members especially put their hands to the work and cordially supported the new Council. The Treasurer's report was also read and adopted, and it was decided that both reports should be printed and circulated. The deaths of the late E. McDougall and B. H. Wightman, Fellows, were announced, and votes of condolence with their families were agreed to.

A ballot then took place, Messrs. C. Gibson and C. Winder, jun., acting as scrutineers, for the election of officers and Council for the ensuing year, with the following result:—Mr. C. M. Gibbs was re-elected president, Mr. C. Hadfield was elected vice-president, Mr. F. Fowler Treasurer, and Mr. C. J. Innocent hon. secretary; and the following gentlemen, in addition to the past presidents, were elected to serve on the Council:—Messrs. R. Fowler, J. Smith, H. W. Lockwood and Thos. Winder, Fellows; W. C. Fenton, Associate; and Mr. J. R. Wigfull and Mr. J. B. Mitchell-Withers were elected auditors.

The President pointed out that Sheffield had been made, by agreement with the Royal Institute of British Architects and the allied county architectural societies, the centre of a province which included Derbyshire, Northern Lincolnshire and part of South Yorkshire, and on his suggestion a draft letter to members of the Royal Institute residing in the province was read and adopted.

An interesting discussion then took place on the general working of the Society, and a number of resolutions were passed for the early consideration of the new Council.

HOLBEIN'S "TWO AMBASSADORS."

IN a letter to the *Times*, Mr. W. F. Dickes narrates the result of an inquiry into the signification of the puzzling picture in the National Gallery as follows:—

In the National Gallery catalogue it is stated that the earliest known notice of this picture occurs in J. B. P. Lebrun's "Galerie des Peintres," &c., Paris, 1792, wherein the author, who had had the picture in his possession, states that "he had sold it, and that it was then in England." During the autumn I set myself the task of discovering whence Lebrun obtained this Holbein. I took with me to Paris lists of such books as I had failed to find in our British Museum library, and to which I had found references. My search in the Bibliothèque Nationale was not very successful, possibly because there is no catalogue accessible to readers, and the officials, although very attentive, are soon tired of the endless demands of a searcher. But in the Cabinet des Estampes, where, by the courtesy of M. Georges Duplessis, the talented director, every facility was accorded to me, I found several of the catalogues I was seeking. One of these was that of M. Beaujon, banker and financier, of Rouen. Its full title is:—"Catalogue de Tableaux et Bustes de Marbre et de Bronze; Vases de Porphyre de Granit Rose et Gris, Porcelaines Anciennes et Modernes; Lustres de Cristal de Roche; Feux et Bras de Bronze doré; Pendules, Bijoux; et autres effets distingués. Après le décès de M. Beaujon, Conseiller d'Etat, Trésorier Honoraire de l'Ordre Royal et Militaire de Saint-Louis; Receveur Général de Finances de la Généralité de Rouen. Par P. Remy et C. F. Julliot, fils. La Vente se fera le Mercredi, 25 Avril, 1787."

There, entered as "Ecole des Pays-Bas, Jean Holbein," I found first the picture which had furnished me the clue; and then:—

"16 bis. Un autre tableau de 4 [?]8 pieds et demi ou environ de hauteur sur près de 8 pieds de large. Il représente Deux Ambassadeurs (MM. de Selve et d'Avaux), l'un Ambassadeur à Venise et l'autre dans les Pays du Nord, avec le costume des nations chez lesquelles ils étaient envoyés et les attributs des Arts qu'ils aimaient. On voit aussi une tête de mort en perspective, à prendre de l'angle gauche du tableau, et qui a l'agrément de ressembler en face à un grand poisson. Ce tableau est du même Holbein, mais la date de l'année n'y est pas. Il est du règne de François I. ou Henri II. Ces deux tableaux sont à considérer."

A pencil note on the margin says:—"Vendu avec le No. précédent, 6co f." (!?)

The remark about the absence of a date upon the picture is not surprising when we remember that Waagen in his supplement says:—"I can only add that the statement of its being dated is erroneous. Mr. Danby Seymour and myself examined it most closely." The cleaning has made this date visible, though even now it has to be sought.

Of course the idea that it represents MM. de Selve and D'Avaux is absolutely exploded. For one thing they were not contemporaries. De Selve terminated his career as ambassador in 1556, and D'Avaux was born in 1595. The probable explanation is that D'Avaux was the owner of the picture. We know that he was a collector, and as ambassador in Germany and the Netherlands would have great opportunities. In a letter dated Münster, August 29, 1646, he reports having dealt for an Albert Dürer. At that time (just before the treaties of Münster and Osnaburgh) his relations with the Palatinate were intimate. We find Baldé, the Jesuit chaplain (1647), living in the palace of the Count Palatine at Neuburg, inditing verse to D'Avaux—writing his "Memmiana," a poetic history of the D'Avaux family, the De Mesmes, and addressing him as a lover and fosterer of the fine arts, "Liebhaber und Förderer der schönen Künste."

One thing in this French description of the picture is particularly noteworthy, namely, that Frenchmen recognise that the costumes are not French, and do not even claim Holbein's fancy medal with the image of St. Michael as their Order of St. Michael. They account for the alien dress by supposing these gentlemen to be masquerading in the dress of the countries to which they were sent. Of course, to me, who recognise the two dresses as just those usually worn by the Count Palatine Otto Henry and by his brother Philipp, who always affected the schoolman's robe at home (he had formerly been rector of Freiburg University), it is difficult to understand how any artist can fail to distinguish between the prim French and the heavier and more careless English and German costumes of this period. And it is more wonderful still that there are any who will not see that the faces are those of brothers and of Bavarians. I have much fresh and weighty evidence which I reserve.

LLANDAFF CATHEDRAL.

THE Chancellor of the diocese of Llandaff has hunted out some information about the difficulties of preserving the cathedral in the eighteenth century. He says :—

The whole history of the poverty-stricken chapter from 1709-51 was, as the records show, a continuous struggle to prevent the cathedral from falling into utter ruin. Besides the many small sums voted in its corporate capacity we find, in 1729, 50*l.* given by the archdeacon personally. In 1721 the Archbishop of Canterbury (Wake) presented a petition to the Crown on behalf of the dean and chapter, and writes on November 2 to Brown Willis that "they will receive the royal bounty of 1,000*l.* I am now endeavouring to put them in the way of begging 500*l.* of the Prince of Wales, and then I think I have done; the rest must be raised among themselves and their friends." Apparently there is no record of the actual receipt of these sums.

In 1732 a royal brief was obtained for a general collection. In virtue of this 1,473*l.* 9*s.* 3*d.* was collected. In addition 931*l.* 10*s.* 7*d.* was subscribed privately by friends, 500*l.* of it by individual members of the chapter. Amongst the subscribers were the chapters of St. David's, Exeter, and St. Paul's. The latter provided 50*l.*, very probably in grateful remembrance of the fact that Llandaff in her poverty had, in 1634, voted 20 marks for reparation of "the cathedral church of Powles," and also 15*l.* in 1673. A list of the subscribers is extant, written by the Rev. James Birt, a prebendary of Llandaff and, later on, manager of the fabric fund.

In 1734 an agreement was entered into with Mr. Wood (architect of the Bath Pump-room, in the style of which he constructed a species of Italian temple in the beautiful but half-ruined nave) to repair the church for a sum of 1,700*l.*

These works were not concluded until 1752, the sums collected being insufficient to meet the expenses. But from 1751 to 1786 there do not seem to be any records of sums collected, and little was done between those dates but ordinary repair.

Though the results may have been somewhat mistaken, the facts show, nevertheless, that the authorities did their best (at a period when, be it remembered, it is said that lethargy had not only fallen upon the Church, but that even the great Welsh national institution itself, the Eisteddfod, nodded and slept), though perhaps their zeal took a somewhat mistaken direction. This, however, would only tend to prove the great work that has been done in the present century at Llandaff Cathedral.

ARCHITECTS AND THE PUBLIC IN AUSTRALIA.*

I WANT briefly to point out some ways in which we can increase our influence upon the public taste, or rather want of taste, in the art and architecture of the country, and I hope I may be able to do so in a practical manner by taking examples that are of everyday occurrence, and if there is nothing new in what I have to say, I claim that it is just as well sometimes to repeat what has already been said or remind ourselves of what we already know, though we may not have actually formed any definite ideas on the subjects or put our almost unconscious thoughts into writing. It has happened to me, as it must to any practising architect, that one is sometimes suddenly pulled up, as it were, in one's architectural train of thought or speech by some simple common-sense criticism or remark by some one outside our profession which may be quite at variance with our ideas, and which shows us that we are not sufficiently in touch with each other, and I have felt on those occasions that we architects live our professional lives too much to ourselves, and that it would be much more to the advantage of our art, not to speak of our own benefit, if we could get away more from our architectural selves and look upon our work, if possible, from the eyes of the public, with the object of making our art more popular. Why should our art not be as interesting and popular a subject to talk about as the sister arts of painting and music? Both of these form almost as ordinary a topic of conversation as Mr. Wragge's remarks about the weather. One certainly does hear new buildings criticised sometimes, but not with the same interest or intelligence shown with regard to a new picture or opera. Now are not we ourselves to blame for all this? When one considers the position of our profession at home in relation to matters of art, and the improvement of the last quarter of the nineteenth century in matters of taste, brought about in the first place by the efforts of such men as Stevenson, Norman Shaw, Burges, Edis and others, and followed on by those who have been trained up under them, and then compare our corresponding position in Australia, one cannot but conclude that we are chiefly at fault. It is the exception here to trust to an architect on a matter of artistic taste, with the feeling to our clients that though it may not be in

accordance with their own ideas they may rest assured that the architect is right. Ladies, who pay more attention than men to the æsthetic side of the question, often ridicule the idea of consulting an architect on a matter of colour, or if they should happen to ask for and obtain good advice, generally, after all, go their own way (often with deplorable and ruinous results), because they have not had confidence in their architect's judgment, though they may sometimes acknowledge after that he was right.

Now if we architects as a body took up the position we should in these matters, more attention would be paid to our advice, and we should be acknowledged the proper authorities, though of course there always will be individual members of our profession fulfilling their own particular sphere ably enough, who have no natural leaning to the purely æsthetic side of the profession, and are content to leave these matters to others. However, most of us, from the very fact that our natural inclinations induced us to take up the practice of architecture, combined with our professional training and associations, should be fitted to become leaders of taste, and those among us who are capable through æsthetic education might, I think, without unduly forcing their ideas down other people's throats, be more assertive when opportunity offers, whilst those who do not feel sure of their ground should qualify themselves by observation and education to give opinions on these delicate matters. Perhaps more harm is done to our professional reputation by repeated errors of judgment from want of knowledge than from lack of any advice at all. One serious hindrance, it appears to me, to our becoming leaders in architectural art is that there is too much pandering to the public taste in the matter of competitions as followed here, for however desirable as a means of educating our juniors in draughtsmanship and ourselves in problems to exercise our brains, not to mention practice in what is known as good business qualifications (but which too often takes the form of unprincipled smartness), they are not, I think, favourable to the erection of well-designed buildings. When, on my first arrival in these colonies eight years ago, I was assisting in the preparation of competitive designs, it was constantly urged upon me to put plenty of "fat" (which I may tell in Australian architectural phraseology means coarse ornamental splutterings) into the elevations, never to mind the cost, and to make them look attractive and busy. And so competitive designs are prepared to please and "take" the fancy of a board of men who, because they have the command of money, are constituted judges of design without their being able even to interpret drawings or realise the effect of buildings when executed from drawings. Such a broad and simple design as that of the Equitable Life would not have had a chance in a competition. There are but few instances in the city where buildings, erected from designs submitted in competition, have been anything approaching a success from an æsthetic point of view, most of our recent business premises that have any claim to good design and taste being the result of commissions given direct to individual architects, and in these instances the public taste has been educated, for I have frequently heard them favourably criticised, showing that, given knowledge of one's subject when one has the opportunity to follow one's dictates, the result is æsthetically the more satisfactory. The public can be taught to appreciate what is really good in our work just as easily as they can be led wrongly by flattery.

The whole basis of good taste in architecture is, in fact, that everything should have a reason for its existence. Look along our streets, and what do you see? Pediments stuck on, not for the purpose of protecting a door or window opening or some feature, but as a bit of ornament in itself; arches put in where they are not required, merely for the purpose of attracting attention; sham dormer gables on the tops of buildings without even a roof behind them or window in their openings; ornamentation stuck on for the sake of itself and not to adorn some feature, and overloading of string-courses, pilasters, caps and bases, columns strong enough to carry six storeys doing nothing. All these errors and many others which must occur to you are in bad taste, because there is no reason for them, and they are just as vulgar in themselves from an artistic aspect as the appearance of a woman in a ball-room decked up with trashy jewellery and millinery put on indiscriminately to attract attention is repulsive to a lady of refinement. We should lose no opportunity to tell the public why these things are bad, to explain why a beautifully-marked piece of marble should not be disfigured by over-much carving or moulding, no matter how beautifully it be executed; why each material should be employed for its specific use, and not made to represent something else. In my paper on "Domestic Architecture," read in the 1892 session, I referred to the advance we had made in recent years in the matter of the designs of our dwellings. But I already see a tendency to run riot in what is termed by the uninitiated "the new style." If we are to guide the public we must not go in for extravagances for the sake of something new. That is not good taste, and we only lay ourselves open to such condemnatory remarks as Mr. Oakeshott and I heard

* From the address delivered by Mr. Howard Joseland, president, at the meeting of the Sydney Architectural Association, published in the *Australasian Builder*.

during the Easter holidays, made with undoubted common sense. With regard to some new houses in a new suburban district it was said:—"What queer houses were being put up, such beastly things all mixed up with tiles and iron, and shingles and bricks, and wood and cement—there was no sense in it;" and in this instance there was a good deal of truth in the remark.

In our home we have great scope for using our influence towards the improvement of taste. Women, whose opinion upon the æsthetic part of building is now generally considered to some extent authoritative as a rule in these colonies, have had no opportunity of studying the use of the decorative arts, by which I mean the conventional application of form and colour as taught at the South Kensington schools, and they consequently cannot see the errors of taste exemplified by such misapplications of art as putting a painting of natural flowers or landscape on tiles in the centre of a hearth only to be smothered up with ashes and fire-irons, or executing a painting on an unsuitable background or material such as a mirror or pearl-shell, or pleating up some piece of drapery covered with some beautiful pattern in such a manner as to entirely destroy the rhythm and harmony of the design. I hope the days of committing such barbarisms as hanging-up on our drawing-room walls such absolute rubbish as rolling-pins and gridirons decked up with ribbons are past, but unless a truer artistic spirit is cultivated there is no knowing how soon they may be revived, perhaps, and just as sanely, with the additions of lumps of gilded pastry and bronzed chop bones as well. It is much to be regretted that the study of decorative art is only in its infancy in our technical schools; for whilst not going so far as our first president, Mr. Seager, as to hold that the architectural profession is suitable to women, there is no reason that I can see why they, as well as men, should not find interest and profitable employment in the æsthetic branches of our profession, or at least study them as a pleasure if not as an accomplishment. Till we have manufactories of such decorative materials as floor and wall-coverings and weavings from the looms, we cannot, perhaps, expect to have a national school of decorative design, therefore it is all the more incumbent upon those who have had the opportunity of gaining knowledge on this subject to make the best use of it for the public good.

TESSERÆ.

Roman Architecture.

THE really good things in Roman architecture of which anything remains to us are comparatively very few. The Temple of Vesta is rather Greek than Roman. Then we have the three columns of Jupiter Stator, three of Jupiter Tonans, the Temple of Antoninus and Faustina, that of Mars Ultor, and the portico of the Pantheon, all six of the Corinthian order; nor have we anything of much value of any other. There are magnificent fragments besides, and in particular some of the marble ornaments in the Forum of Trajan raise a high idea of its beauty and perfection. But there is no other building which can be considered as a model. The erections of the four first emperors were generally in good style, and a sentiment of correct taste and feeling existed till the time of Trajan. Under that emperor the productions of Apollodorus are decidedly superior to most of the edifices which preceded his time, but the artist and the purity of the art were destroyed by Hadrian. Some traces of beauty remain under Severus, but these are gradually lost between him and Constantine. A common country mason in England would make as good designs, would draw the architecture with as much truth and correctness and execute the ornaments, sculpture included, as well as the artists employed by Constantine. The degree of degradation to which the fine arts had fallen in that period is a very remarkable phenomenon in the history of the human mind, for the empire, though torn and suffering in many parts, was still great and powerful, and both for individuals and for the public the arts must still have been exercised. Yet the architects of Constantine's reign could not find workmen who could give the mouldings a regular curve, or even preserve them in a straight line or form an even surface.

The Temple of Vesta at Tivoli.

The cell is formed of *opus incertum*, which has been described by Vitruvius as a masonry of small pieces of irregular shape, fitted together and united by mortar. Some writers have supposed that by this term he meant the Cyclopean walls, which are constructed of large pieces without mortar, but his description is sufficiently precise to leave no doubt of his meaning. Of this *opus incertum* we have reason to think that it was in use in the time of Sylla and probably much before, and the complaint of Vitruvius that it was in his time giving way to the *opus reticulatum*, which though neater was less strong, together with the want of existing remains which are known to be of later date, will justify us in concluding that it

was discontinued in the reign of Augustus. Now the construction of the walls and the forms of the capital very much resemble some fragments remaining at Palestrina, belonging to the Temple of Fortune, which we know to have been restored and greatly enlarged by Sylla, and at Pompeii there are capitals of a similar taste, but evidently much prior to the earthquake which preceded its final calamity, and putting all these circumstances together, we may with some probability assign this building to the time of Sylla. These capitals are not ornamented with the leaves either of the acanthus or the olive, but with some which rather resemble those of the *Verbasicum sinuatum*, and neither they nor any part of the building offer the least trace of Greek taste as distinguished from that of Rome. We do not find at Rome any examples of similar capitals, except an unappropriated fragment or two of peperino, which may have belonged to the same period. Within the cell is a recess, which seems to have been the work of later ages. It has a large doorway and a window, both of which are considerably smaller upwards. The material of the *opus incertum* is a sort of tufa, but the dressings which surround the door and window, together with the external order, and the continued pedestal on which it stands, are of a coarse, calcareous, fresh-water deposit, much resembling travertine. This, in the columns at least, and perhaps everywhere else, was covered with a very thin coat of fine, hard stucco, and the *opus reticulatum* was probably covered with stucco also, but it must have had more substance, or it would not have concealed the little inequalities of the work below. The cornice has no modillions, and the dentil band is uncut; otherwise it would have been a regular Ionic entablature, as directed by Vitruvius. The columns have settled a little outwards, as is evident from the openings in the entablature. Here are sufficient vestiges of steps to prove that they descended laterally, and were not brought straight out, as they are usually published, but there is not enough remaining to make out distinctly all the particulars.

Stone-Carving in Paris.

The London carver of stone rarely works from a model, more often from a sketch, and not infrequently without either; the Parisian always has a model. The Londoner, with plumb-bob, rule and compasses, generally makes an approximate copy of his model when he has one; the Parisian, by means of a mechanical contrivance called a pointing-machine, makes an exact copy. The Parisian system no doubt has its advantages, but from the English workman's and from an artistic point of view, the Londoner's method is far the best, throwing the workman on his own resources and developing whatever individuality and artistic feeling he may possess. It has also the not unimportant merit of being the quicker method. The material used in Paris is a cream-coloured soft stone, somewhat resembling Bath stone, but apparently freer in working. In London, as is well known, every variety of stone is used, from the soft Corsham to the hardest of Portland among the lime-stones, and from the softest of red grits to the hard yellow gritstones of the North of England. This has developed a more useful pattern of tools than those in use in Paris. The hard stone and marble tools are similar in both countries, but the French soft-stone tools would be thought useless in England. The block of stone is chopped with axes as near to the size required as can safely be done, and the carving is then produced with wooden-handled tools and iron hammers, the English pattern of wooden mallet and mallet-headed tools being unknown. It is then scraped over with tools known in England as scrapers, and finally finished with a variety of rasps called "riffers," or "riffleur râpes." These riffers are, though seldom required, unobtainable in England of native make comparable with the French, being generally so badly shaped as to be almost useless, and this applies not only to the riffer rasps as made for soft stone, but to the riffer files as made for marble, a foreign variety known as Roman rasps being far superior.

Manchester Cathedral before Restoration.

The exterior of the church, from the decay of stone where it had not been laid upon its proper bed, had been extensively repaired from time to time during the close of the seventeenth and throughout the eighteenth centuries, and not in the best style of Gothic architecture. But the greatest havoc was wrought in the interior early in the present century under a pretext of improvement, when the beautiful columns and arches of the nave, the superincumbent clerestory, the great choir arch, the piers and arches of the outer north aisle or Trinity chapel, and the tower arch and wall above it were hacked over with a pointed pick, and then coated with cement three-quarters of an inch in thickness. As an inevitable consequence the mouldings and architecture were ruined and thrown out of all proportion, and the stability of the structure itself seriously imperilled, for on removing the cement it was found that some of the springing stones of the nave arches had been reduced to an area of only 14 square inches on their bed, on which the vast superincumbent load was borne. Happily,

in two columns and arches sufficient portions of mouldings remained to enable a complete section to be made, from which the whole of the arcades have been carefully restored. Nor did the masonry only suffer, for the ancient roof of the inner aisles of the nave, elaborately moulded and having richly-carved bosses at the intersections of their timbers, were hacked in a like manner, and after having had multitudes of nails driven into the moulded beams, were coated over with plaster and the oak bosses replaced by cement substitutes. The chief object of these alleged improvements was the erection of galleries, during the construction of which the transverse arches and elaborate screenwork defining the several chantries, and also the inner walls of the south porch, with its parvise and groined vaulting, were swept away, and the whole thrown into an unbroken area surrounded by huge galleries on every side of the square. The rich screenwork, with the magnificent rood-screen (except a small portion now fixed under an archway leading to the Ely chapel), had completely disappeared. In place of the divisional walls and arches of the southern chantries, and in order to support the roof, a range of columns and arches was constructed in hewn stone, afterwards coated with cement to correspond with the rest of the interior.

Construction and Decoration.

The notion has arisen, that if the architect takes good care of the useful the beautiful will take care of itself. New constructional necessities and discoveries have been asserted, by architectural critics of respectable standing, to have constituted, not only the germ, but the whole essence and form of each new phase of architectural character; and authorities afford examples of many confused and self-contradictory statements, in which the nature of decoration, and all that relates to effect, are treated as wholly subordinate to, and exponential of, constructive obligations. This misconception has been the reaction of the opposite and far more pernicious error of regarding all decoration as arbitrary, unmeaning and independent of construction. The error prevailed for centuries, and originated and completed the decay of every great style of architecture; it hid the discharging arch above the Roman doorway, with the falsehood of the sculptured architrave; it began the destruction of the Pointed style by the introduction of intersecting tracery lines; it brought about, by an easy gradation from forms either insignificant or unnatural, the ruinous contradiction of imitated materials, giving to Raphael's Pandolfini Palace its cornice of perishable wood; it blinded the architects of the Cinque-cento manner in England and France to the absurdity of facing Gothic masses with spectral reminiscences of Greek details. It is demonstrably wrong to regard the leading transitions of architectural style as having consisted wholly, or even mainly, in the fulfilment of new constructional necessities, and the effects to the eye as having been no more than the simple, unforeseen and unintended sequences. Constructional change, as an unavoidable condition to great novelties of effect, must have preceded such novelties in order of time. But who will venture on the absurdity of maintaining, for example, that the prodigious height of the naves of Beauvais and Cologne, and still more that of the spires of Salisbury and Strasburg, sprang from any necessities in the new construction, instead of the success and establishment of the new construction being chiefly owing to its capacity for producing this and other visual effects, which remained impossible till the round arch shot up into the lancet, and the ponderous masses of Roman and Lombard wall dissolved into the fairy framework of windows and buttresses? The very birth of the Pointed style seems to have been owing to the purely artistic element of architecture, to the desire for loftiness and magnificence for their own sakes, and not to any incapacity of the preceding style for the fulfilment of all ordinary purposes of church building. It may, however, be admitted as an important principle, perhaps the most important principle of architecture, that the peculiar artistic expression in every great and pure style, as the Egyptian, Greek, Lombard, Moresque and Northern Pointed—and, in an inferior degree, the mixed expression of less perfect styles, as the Roman, early Byzantine, Venetian-Gothic, and Cinque-cento—is always in a peculiar and harmonious relation with the manner of construction adopted. It is in every case an expression which could not be obtained legitimately under any other condition of construction.

The Cathedral of Rimini.

The cathedral of Rimini was restored and altered by Leon Battista Alberti. The works of this artist are few, and lie rather out of the beaten track, and they are particularly interesting, not merely as he was practically one of the earliest restorers of Roman architecture, but as he was the first who reduced it into a system by his writing. The old building was of pointed architecture, but it is so completely covered by more recent work that we cannot attempt to form any judgment concerning the time of its erection from the appearance of what remains in sight. The front and the one flank which is exposed to public view are entirely by Alberti, and an inscription on the frieze gives us the date of 1450. The front consists of four

columns, whose order is a compound of Doric and Ionic, neither of them well understood; and three arches, of which the middle is the largest and contains the doorway, while the side ones are merely shallow recesses. These columns are set upon a continued basement, which is unfortunately cut through by the doorway; but in other respects the proportions are good, and suited to the style adopted. The columns appear too far apart, if they were introduced as essential parts of the building; but Alberti has used them as Palladio has so frequently done, as ornaments, which may indeed contribute to the firmness of the edifice, but are not absolutely necessary to its support, and the entablature, consistently with this view of their office, breaks round them. The upper part is not completed, but we learn from a medal that there were to be pilasters over the two middle columns below, supporting an ornamental arch, with a portion of a circular pediment on each side. It is probably better that it has not been executed; but here also we find something of the disposition afterwards followed more successfully by Palladio. The flank is much better than the front, from the beautiful simplicity of its seven equal arches, rising on insulated piers; each pier has a panel, which, though they are quite shallow, is a great defect. Above each pier there is a circle of porphyry, surrounded by a wreath, and at a moderate distance over these the entablature corresponding with that of the front. In each arch there is a stone sarcophagus, and the whole is elevated on a continued basement. The only fault in the composition is the panelling of the piers. Everything else is beautiful. On the inside the arches of the nave are pointed, almost the only circumstance retained of their original form. The piers are now ornamented with architraves and Corinthian pilasters, the former of which are cut up by a multitude of small mouldings, but each still retains the character of an architrave. The pilasters are divided in their heights, like towers of several storeys, composed of a succession of distinct architectural compositions. We wonder to see the effects of so pure a taste without, combined with such puerilities within. The materials of this church are said to have been drawn from various Roman antiquities, and particularly from the church of St. Apollinaris at Classe, but there is no appearance of any ancient fragments.

Italian Monuments.

Italian monumental architecture, with some favourable exceptions, is composed of little parts, and highly ornamented. It is more broken than that of their larger edifices, often handsome, and with great beauty and delicacy in the details, but without anything magnificent or impressive; hardly ever with any character as monuments, except that as the eye becomes accustomed to see them in this form, we obtain an habitual association, and sentiments of death and eternity may be awakened in the mind; but without such habits the style would rather seem accordant with scenes of temporary gaiety. Yet in all countries, and in all ages, it has been customary to decorate tombs highly and even splendidly.

The Opisthodomus of the Parthenon.

The opisthodomus, so long supposed to be a vestibule preceding the temple, was in the back part of the Parthenon. Its width is the same as that of the temple, and its length 21 feet 6 inches, or nearly one-third of the cella. By some inexplicable error, Stuart, Chandler and others have represented, both in their text and plans, that the opisthodomus was supported by six columns, placed in two rows. There never were but four. Brönsted has so given them in his plan, and the fact has been more recently proved by Leake and Travers. One of the columns having been broken, the Turks erected in its place a square pillar of masonry, which, as well as the three columns, is now demolished. The latter, according to Stuart, were of the same dimensions as those of the smaller order in the peristyle. In the opisthodomus besides the money proceeding from the public revenues, and the contributions of the Grecian cities, 1,000 talents were always kept in reserve to meet unforeseen expenses of the State. At the beginning of the first Peloponnesian war (432 B.C.) when the power of Athens was at its height, 6,000 talents (1,296,000*l.*), according to the Abbé Barthelemy, and 9,700 talents (above 2,120,000*l.*), according to Raoul Rochette, were deposited in the opisthodomus. The names of all the debtors of the State were inscribed there. Private individuals were accustomed to deposit sums of money there which they were afraid to keep at home; it was also the repository for offerings made for the goddess, and valuable spoils taken from the Persians, part of which was the throne with silver feet, on which Xerxes sat to witness the battle of Salamis. Other trophies, shields taken from the enemy during the Median war, were suspended on the architrave outside the temple, and alternated with bronze inscriptions, if we may judge by the marks of the nails which held them. The two guardians of the treasure deposited in the opisthodomus of the Parthenon were Jupiter and Plutus, the god of riches, represented with wings, and, by an exception peculiar to this god, not deprived of sight.

NOTES AND COMMENTS.

WE have lately drawn attention to the growth of a disinclination among municipal and other local authorities to be troubled with many competitive plans for new buildings, and pointed out its danger. The same tendency is being exhibited in dealing with builders' tenders. The case of the proposed asylum at Horsham is an instance. According to an approximate estimate, that building will cost at least 150,000/. The committee having charge of the arrangements announced to the County Council, through the Duke of RICHMOND, that only a limited number of tenders would be invited. One reason given for the proposal was that if the competition were general, the Council might find themselves saddled with a contractor who would be unable to complete the work. But that contingency might surely arise if the competition were left between a pair of contractors. It is the business of the Council, their architect and lawyer, to provide as far as foresight will enable them against loss from a breakdown. Another member said that the best builders would not take part in an open competition. We often hear of a resolve of that kind, but it is mere "sound and fury, signifying nothing." There are few, if any, of the largest builders who could afford to let an opportunity of gaining a job of 150,000/. go by for the sake of dignity or etiquette. The Duke of RICHMOND was more frank when he said that, if unlimited competition were allowed, there would be no end to the number of tenders they would receive. It is onerous that his Grace and other Sussex noblemen and gentlemen should have to wade through documents of the kind, but they should not have accepted office unless they were prepared to encounter all its troubles. As a fact, unlimited competition does not necessarily mean an unusual number of tenders. Builders are too shrewd to run the risk of attempting contracts which are beyond their strength, and there is, moreover, the difficulty of finding sureties to uphold them in excessive risks. Financial societies, in ignorance, may be ready to attempt constructive feats without a chance of obtaining profit, but in such cases there is generally security enough to compensate a building owner. The Sussex committee apparently wished to restrict the competition to three or four firms, which, we admit, would be the pleasantest way of discharging a public duty. The Duke of NORFOLK, who has had no small experience in building works, insisted on at least eight firms taking part in the contest. Another member proposed twenty, which would be barely sufficient for a work of the kind. LORD LECONFIELD and Mr. W. E. HUBBARD suggested the number should be twelve. As opinion was decidedly against a sacrifice for the sake of securing the ease of the committee, the Duke of RICHMOND announced that, after what had passed, he had no doubt that the committee would invite twelve firms to send in tenders. Public bodies and, we may add, private clients, will consult their own interest by taking a lesson from the action of the Sussex Council. If contracts are to be a sort of pastime, there is no doubt the fewer the contractors the stronger the certainty of attaining that end, but pastimes generally mean outlay, and, if economy is desired, clients will find there is an advantage in allowing many builders to struggle for the contract.

THE Metropolitan Building Act, 1855, section 27, sub-section 4, prohibits the erection of buildings for the purposes of trade or manufacture containing more than 216,000 cubic feet, unless divided by party walls in such a manner that each division of the building does not exceed the above-mentioned number of cubic feet. The London County Council's General Powers Act, 1890, section 29, gives the Council power to approve, under certain conditions, of buildings for trade or manufacture containing more than 216,000 cubic feet, but not exceeding 450,000 cubic feet. These provisions are proposed to be re-enacted in the London Streets and Buildings Bill promoted by the London Council, and now before a committee of the House of Commons. The Royal Institute of British Architects object to the expression "cubical content," and wish to substitute for it the words "cubical extent." This alteration was agreed to by Mr. LITTLER, Q.C., who opposed the Bill,

with the remark, "I raise no point upon that; if it amuses the architects, it does not hurt us." The change is made with a view to meet a difficulty as to the mode of measuring the cubical contents of a building, whether the walls and the space under the roof should be included in or excluded from the measurement, but it will not have that effect. The words "cubical content" have a definite meaning, and there ought to be no difficulty with regard to them; they mean the space contained within a building exclusive of the walls. All measures of capacity are exclusive of the vessel in which they are contained, and in measuring the cubical contents of a building the walls should be excluded. The word "extent" is not an appropriate word to define cubical capacity; it is derived from the Latin *extendere*, "to stretch out," and is properly applied to superficial admeasurement alone. In the absence of any direction as to the manner in which the cubical extent is to be ascertained, the same difficulty will be experienced as is said to prevail under the present Act, and nothing will be gained by the substitution of a word. When the Bill arrives at the House of Lords and is subjected to the searching scrutiny with which it has been threatened, the Peers may perhaps find time to take up the question of contents or non-contents as being more familiar to them than the humdrum way of putting the question in the House of Commons.

THE appeal in the action that arose out of the sale of Farringdon Market has been heard and determined. The circumstances were novel, and have been already described in this Journal. The property was purchased in March 1892 at an auction by Mr. H. T. TUBBS for 98,100/., and he paid 10 per cent. deposit. In the conditions of sale it was stated that if the balance was not paid on June 24 and the purchase completed—unless through wilful default by the vendors, the Corporation of London—interest at the rate of 5 per cent. should be charged to the purchaser. It was discovered that the title to a part of the property was erroneously described, and the sale was not in consequence completed until February 1893. The vendors, however, argued that they had made out their title by September 29, and claimed interest to that date. Mr. Justice CHITTY took the same view, and considered there was no wilful default on the part of the Corporation. Mr. TUBBS appealed. It is not often that Mr. Justice CHITTY's decisions are reversed in a superior court, and this case was not one of the exceptions. As we pointed out at the time, it is extremely difficult to prove "wilful default" on the part of a Corporation. There could be no doubt there was negligence or oversight in describing the property as being acquired under the authority of one Act of Parliament, when one-tenth of the area was a much later acquisition. But neither Lord Justice LINDLEY nor Lord Justice LOPES, while admitting the error, could accept the theory that it arose out of a default that was to be considered as wilful. Lord Justice KAY endeavoured to look at the circumstances as they would appear to the purchaser. "The purchaser urges," said his lordship, "that the default was 'wilful,' because the person who made it willed not to make the search which it was his duty to the purchaser to make, before making the positive statement in the conditions. I am not able to find an answer to this argument which is satisfactory to my mind. If the vendors had not made the positive statement as to all the land being held under the statute referred to, or if, having made it, they or their agent had taken some steps to verify it, and had in so doing committed a *bona fide* mistake, the case might be different. But, according to the evidence, no attempt to verify the statement was made, and the omission to do this was not only a 'default,' but was a 'wilful default,' because it was a deliberate neglect of a duty to the purchaser which the vendors, by making the positive statement, voluntarily assumed." Lord Justice KAY, however, considered that the purchaser had, by his acts, contributed to the delay in completing the transaction, and on that account he agreed with his brethren in upholding Mr. Justice CHITTY's decision. The result is not satisfactory, but it should be accepted by builders and purchasers of building estates as a warning of the risks they incur when they accept the responsibility of proving that somebody's defaults are wilful.

THE ARCHITECTURAL ASSOCIATION.

A MEETING of the Association took place on Friday evening, Mr. E. W. Mountford, president, in the chair.

The following were elected members:—Messrs. R. Anson, N. M. Doncaster, E. H. Rouse, A. B. Venables, W. J. Walford and F. C. Young.

The annual dinner it was announced would take place on the 31st inst.

The house list, as arranged by the Council, was formally nominated, Mr. Pite and Mr. Cooper being nominated for the office of vice-presidents by certain members of the general body. Messrs. Brodie, Wonnacott, Greenop and Whately were appointed scrutineers of the ballot.

Mr. HENRY LONGDEN then read the following paper on

Practical Hints on the Working of Wrought-Iron.

Wrought-iron is one of the most useful and necessary materials which the needs of man have discovered. It has been used from early ages, and its widespread use is easily explained from its strength in proportion to its bulk and its cheapness. It has been used for railings, screens, balconies, balustrades, chains, anchors, cramps, stanchions, chests, all kinds of supports, implements for use about fires, hinges, locks, window fastenings, and numberless other uses which would be tedious to recapitulate.

The material, too, is one which has to be worked with heat in all genuine smith's work, and it requires strength of arm, sureness of eye, dexterity of hand and great judgment. A little over-heating in the fire, a little over-hammering and the metal is spoiled, and the work has to be done over again. There is something fine, strong and masculine about good iron-work, and each curve, swell or play of line in a piece of forged work has to be got by good hard blows which the finished work expresses to the mind, although the observer may not know what effort has gone to produce the result he sees.

The iron is now bought from the manufacturers in bars or rods, and in this material especially quality is of great moment, as ironwork in connection with architecture has usually some office to perform in which strength and lightness are both sought for; the quality of the iron should be looked to, as inferior iron has neither the strength nor the power of resisting the destructive effect of the atmosphere which good iron has. There is a point, too, which causes much difference between old and modern work, in the regularity of the making of the iron bars or rods. In old times these were drawn out on the anvil from lumps of iron, and now they are rolled between what are called "rolls" of iron with grooves turned in them. The hot metal is made to pass through the rapidly-revolving "rolls," and a bar 12 feet long will be quite of the same section and size from end to end, whereas the bar made by the old process would be irregular in thickness, which, in certain kinds of work, adds charm to the design. I have found it necessary in some work to heat and hammer the bars to give them some of the irregularity of surface of the old work.

Before beginning his work the smith takes his bar of iron and examines it, springs it by shaking it, and tests it generally as to soundness and quality. For bars in railing (such as some here) the iron has to be looked along to see that it is out of twist and straight. He then heats the bar in the fire and brings it to the anvil, on which he may work it alone, or with a "striker" or "drummer," or with more than one if the work is heavy. The smith directs the "strikers" with his hammer, which is a lighter one, how and where they are to strike with their heavier hammers, and he can indicate the force of the blow he wants. The working together of two or more men on the glowing mass of iron drawn from the fire, the perfect understanding without words which they show, and the shaping from the bright red mass of the object to be made, passing through cherry red to dull red, and finally to a grey blue, is one of the pleasantest things I know to witness. The tractability of the material and the way in which a fine and delicate object can be made out of a rough mass, with almost no waste of material, is a great lesson in the superiority of mind over matter. I know of no material which exemplifies this in a large way so well as iron.

If a bar or rod is to be used in railing, with a head, such as is seen here, a thicker piece is welded on to the bar, and it is drawn down with the hammer, as you see in the specimen, to a taper shape or to any other shape that is required by the design. Where the heads are drawn smaller, as is the case

with the square bars, and there is great repetition, a "swage" or "stamp" is made, which makes them more readily and makes them all alike, which is the more economical but less artistic way of doing the work. In St. Helen's Church, Bishopsgate, after the numerous changes and sweeping away of monuments, there are some good examples of this kind of work, notably round the tomb of William Kerwin, where very light iron, only $\frac{3}{8}$ -inch square, set angleway, is made into a close railing, the heads are of various lengths, and the forged collars and finishing knobs at different distances in the heads, yet the effect is good and free. Sir Julius Addiman's tomb-railing, of which I made notes in 1890, appears to have gone. This was a stronger railing, still very close, and with fine twisted corner pillars, made of four $\frac{3}{8}$ -inch square bars twisted together, with square moulded caps and bases, and long twisted pinnacles finishing with balls.

The mode of making the rails or the long horizontal bars for railing varies much, and the effect to be got by these is worth consideration in designing railing. The simplest and cheapest way is to take the ordinary flat bar and punch out the holes by machinery. This is almost of necessity the plan used for large quantities of railing on account of cost, and the holes punched may be square or round. When the work is smaller, as in internal grilles or small gates, the effect of swelling out the rails, as shown in the examples, with round swells to suit round bars, or with swells for square bars, set either square-way or angle-way, is richer. The perspective, in which we really always see this kind of work, is much enriched by the breaks in the horizontal lines, and the extra cost caused by swelling out the rails is found to be well bestowed in greater elegance of effect. The rails used in this way need not be so large as when straight flat bars are used; the width of the iron must be enough to allow of the holes being punched without danger of bursting out the iron on each side of the hole, whereas in these examples you will see that a rail $1\frac{1}{4}$ inch wide is swelled out to $2\frac{1}{2}$ or even 3 inches where the bars pass through it. If a flat straight rail were used, not less than $2\frac{1}{4}$ inches would be needed for the holes for $\frac{7}{8}$ -inch square bars such as you see.

The effect of square upright bars set square-way or angle-way is also worth considering in designing railing and grilles. The perspective in which one sees them has the effect of making the square-way square bars look the richest, as you get the two sides wherever you see the railing. When the square bars are set angle-way you may see practically only one side, and the effect is poorer, though the diagonal projections in the rails make a kind of decoration. The round bars have a pleasant softness of light and shade, but where strength of effect is wanted square bars are to be preferred.

For gates strength in the framework and staying with horizontal lines is to be recommended. In the way of treatment of the iron, the grain or the lamination of the metal in the lengthway of the iron must not be forgotten. The bracket-piece I have here, which forms the end of a horizontal bar of a gate, with its tenon prepared to rivet into the mortice to be cut into an upright bar, looks a simple and straightforward piece of work, but it has taken a good deal of making. It is first made as A, with a hole through it; the tenon is then rivetted into it, the way of the grain being the lengthway of the tenon (see B), and then the remainder of the shoulder and the rail to form the horizontal bar is welded to this piece of work, making what you see. I have known instances of smiths attempting to cut the tenon out of the solid lump, and so shaking the iron in the process that the grain was destroyed and the tenon fell off. If this does not happen the iron is weakened, and that which should be one of the strongest parts of a gate, having to resist twisting, thrusting and sagging, is not able to do its work adequately, and the gates will give way much sooner than they would if well made. If you examine this piece of forged work you will find a slight indication of the weld I have described. This piece of work, like the other specimens I have here, is practically as it left the hammer, no filing having been done, except a little with a rasp where it was necessary to get off the scale which the iron throws off when it has been heated. I may here say that hammer-made, as contrasted with filed-up wrought-iron work, should always be sought for and required. This remark applies to black work; where the ironwork is polished, which is a very beautiful treatment for small and very rich work, the whole surface has to be filed and finished up with emery.

The treatment of iron in forming scrolls is one of the characteristic ways of working this metal, and one to which no other metal or substance with which I am acquainted will lend itself. The iron is taken of an agreed size, and is heated and drawn out, thinned, either spread in the thinning or kept to the same width throughout, and then rolled up entirely by the eye and the skill of the hand. There are steel templates made, round which these scrolls can be turned, but the result is, as might be expected, a dead uniformity and a loss of all life in the work. There are here examples of three ways of forming scrolls, of which each has merit. The more the iron is drawn out the closer it may be rolled up to look well.

These scrolls often spring from stems which are prepared with short starting-pieces (see example), and the scroll is welded to the starting-piece, care having to be taken to make the welding places at such distances from one another that they are not too often heated in the fire during the weldings. The end of this stem is shown "scarfed," so that a bar can be welded to it without a diminution of bulk at the point of welding. The two bars to be welded are brought to a white heat in the forge, are then laid together on the anvil, are brought by gentle blows of the hammer into their right places, and are then, by strong blows, firmly united, so that a good weld makes of the two pieces of iron one. This quality of the power, without any other substance being employed as solder, or making the two things indissolubly one, is a special quality of iron.

There is here a piece of work showing the forming of scrolls, the welding together of two pieces in which the main line of the design runs in the same direction, and the welding on of a hammered leaf. The preparation for welding the scroll is done similarly to the piece with the leaf in the centre.

The forming of the forged leaves is an interesting part of the work. A blank (A) is first made, which you will see is well hammered. It is then hammered into a V-section (B), and you will observe the force of the strokes necessary to bring the iron into the curved form at the edges of the sheath. It is then worked further, serrated, the eyes cut and modelled, until you find a well-modelled leaf like that before you. This is a special branch of the work, as you will see, and the fine, bold modelling requires much skill and practice. In much of the work done, both in older and more recent times, the leaf-work is hammered out of thin sheet, and is then fitted with "checks" filed out of the main lines of the work, so that the thickness of the leaf shall not break the suavity of the line. The leaf is then rivetted on, and often brazed too, but that is not the best smith's way of doing work, and is not so enduring, as the thinner iron is sooner destroyed by rust.

There is here another piece of work in which the bar is drawn down and twisted at the top, and two leaves forming a sheath are welded on it. You can just see where the thickness of the leaves melts into the stem, and just this amount of variation in the line gives life and vivacity to the work.

I do not follow out this part of the work, as the fine beaten work in iron, black or polished, which can be done would lead me rather away from smith's work, which is pre-eminently wrought-iron work.

Another treatment of iron is carving it as you see in the head here and in the snake. This kind of work lends itself well to grotesques. It was carried out in the Renaissance times with great delicacy and beauty, but while it will add interest to small works, it is too difficult to be worth doing, except in a small way, in a material which is so intractable, which is only another way of saying unsuitable, for the purpose.

The small quatrefoil is an example of welding, first of each trefoil point with the two branches springing out of it, and then of bending the arms and welding them together in the centre of each lobe of the quatrefoil. This work has to be done very accurately when these quatrefoils have to be banded together to make sheets of work, but it may be done so that each quatrefoil has an individuality of its own, and that the dead mechanical uniformity which is the blight on so much modern work may be avoided.

There are intricacies of halving bars together, by which is meant filing out of each of two bars meeting one another mortises, so that when put one with the other the two bars take up only the room of one, but this weakens the iron very much, and is not to be recommended. It was principally done in work where a flat surface was desired.

Twisting iron is another characteristic treatment. It is to be remembered that a twisted square bar takes more room when twisted than when plain, and it cannot therefore be passed through the hole which would take the plain bar, but it is possible so to reduce the bar to be twisted as to make it very little if at all larger than the plain bar. When twisting is done in large sizes of iron this reducing before twisting must be done, otherwise the twist looks coarse. Twists of two, three, and even four strands may be done, and in some of the late Mediæval work a good effect was got by grooving the iron bar and then twisting it. There is a good example of this in the ante-chapel of St. John's College, Cambridge. Round rods of small size can be welded together and twisted—indeed, a small form of this, swelled out in the centre, has become a commonplace in the shops, and is, as always in such cases, greatly misapplied. I have seen it used as short pillars in a fender, while the very reason for it is either that it is wanted to relieve what would otherwise be a dull length of bar, or as a termination like a handle. It is one of the small clevernesses which are easily overdone.

The setting out of ironwork for staircases where there are curves and vamps is difficult, and a running pattern rather than one which sets out in panels or smaller repeated parts is to be avoided. The difficulty can be overcome, but the result does not seem to be worth the trouble required to attain it.

I have here some examples of old and modern work which are exemplifications of points I have named.

The grave cross is a piece of Swiss work, and shows welding and scrollwork, split at the ends, moulded and spread out into rams' horns in a manner very characteristic of late German and Swiss work. It is too florid in style, but is a marvel in its way.

The oblong panel is also a piece of Swiss work, and is noticeable for the fine design of its main lines and for the way in which the iron is beaten out thinner from the main thickness, is formed into leaves, then goes on again as flat iron in a reduced form, and finally finishes in a leaf and a sharp point. The thistle suggestion is here very plain, but the thistle is nowhere so used as to become naturalistic: it always keeps within the bounds of ornament.

The bracket is English work, and is a good example of the seventeenth and eighteenth-century work so common about London. The little naturalistic touch of the bay-leaves among the set lines of the scrolls is very pretty.

There is a panel of Mr. Sedding's work here which was made purposely with great irregularity in the scrolls and in the ornaments. The only binding points in this work are the points of contact of the scrolls, and a general similarity of shape in the scrolls is kept, but after that the smith was left quite free to form the work to his fancy. Looked at in the full-face way it looks very irregular; but if you were to see this work forming a side screen to a chancel, where one of our best late architects had had the chancel screen made in an admirable manner of strict regular Mediæval design, you would see where the life was in the ironwork.

The panel with two large roses is a piece of Mr. Sedding's work for Holy Trinity Church, Sloane Street. It is an epitome of that work, which he said was the best ironwork he had done. In its abundance of line, in its profusion of ornament, and yet in the subordination of the smaller to the principal parts, it is a good example of Mr. Sedding's work. The screens at the side of the chancel steps are of plain bars, with a wonderfully curved and ramped capping; and up the centre of this comes a free undulating stem, which rises above everything and bursts out into sprays and blossom, as one has seen a bunch of wild rose rising up out of a hedge. Only a master like Mr. Sedding could do such daring things, but he justified himself by his work.

The small panel of quatrefoils is a study I had made from a piece of Venetian work of a rather smaller size. It is a good example of their Gothic ironwork, and you will find the scrolls forming the quatrefoils are not regular, nor are the points clasped in the bands, nor are the bands, though I fear they are more regular than the old example from which it was studied. The lacing of the bands into the frame is an interesting point in this work, and it makes it very strong.

I have here in the ground-floor vestibule, by the permission of Messrs. Florence & Satchell, a piece of ironwork forming part of a railing for the front of a building. It exemplifies many of the matters on which I have spoken, such as the heads of the square bars drawn out by the hammer, the welded work in the pilasters and the drawing-out of the iron in the scrolls. The banding of the work together, and the contrast of rich and plain, the change from the plain upright bars under the plain uprights and the contrasts of rigid and curved lines are points in the design to which I would draw your attention. I am sorry that the piece of work is too large to be brought up to this room, and if less had been shown you would not have been able fully to appreciate the design.

Much ironwork is being done now, more than has been done for many years past, and there is a plethora of the pretty and meaningless work. I was sorry to see at an exhibition promoted by the Blacksmiths' Company lately very little work which I should consider really smith's work. Fire-screens, lamp brackets and other small things were the staple of the exhibition, and florid, meaningless ornament was abundant. It may be that in a room it is difficult to show important pieces of work, but in only one or two cases did I see any indication of feeling for wrought work, by which I do not mean thin iron bent cold into intricate forms, but works formed in the manner I have before described. This kind of work lends itself to making combinations of scrolls, flowers &c., of stock sizes, and we are now offered flowers, leaves, bosses and other ornaments wholesale. I need scarcely say here that this is not the way to good work, and that the work of old times, which we study and admire, and on which we found our own work, without direct copying, of course, was not done in this way.

There is great fashion in these matters. I remember when Gothic hinges, often of very fine design, handles and certain screens in cathedrals were the only ironwork made. Now I am sorry to say that the making of hinges is less in fashion than it was. The making of a hinge which clasps both the front and back of a door, with the knuckle thrown out to suit the pin, and the work in front of the door well drawn out, thinned down and hammered into ornamental form, is one of

the best tests I know of a good smith. There are still fine screens made, but the domestic use and the ordinary use of ironwork has so increased that no skilled man should want employment.

If architects will require good work they can get it, and the understanding of the points of ironwork practically is much greater than it was some years since.

Mr. ARTHUR KEEN proposed a vote of thanks to Mr. Longden for his paper. The paper he had liked, especially because Mr. Longden had treated of methods of working. Mr. Gardner's lecture on pewter at the Society of Arts had nothing as to how the work had been done. Architects should get ornament by means of natural and unostentatious treatment of materials. Builders had hard work to follow architects who designed in the wrong way. The ironwork of the Amboise balcony was of most simple but effective design. The swellings of the joints and the passing of one set of bars through the others and reversing the process was, however simple, most effective and economical as to cost.

Mr. W. H. WHITE seconded the vote of thanks. He called attention to the excellent old railings to be seen about many houses and in the squares of London. Work also in the provinces and in Sussex should be studied, and then there would not be seen to be much meretricious work.

Mr. E. GREENOP alluded to lock and hinge-work in South Kensington Museum. Looking at Mr. Sedding's beautiful iron panelling, he supposed that Mr. Longden had meant to say that such design in metalwork was to a certain extent justifiable.

Mr. H. A. SACHELL asked for information as to how they could produce the best effects at the least cost; also whether there was any reliable process for preserving ironwork.

Mr. H. W. PRATT said he was glad to hear Mr. Longden condemn over-elaboration in ironwork, notwithstanding that much had been designed by eminent architects.

The PRESIDENT said that the use of iron could be carried beyond proper limits, and it was possible, as in Mr. Sedding's work, to get outside the proper use of the material by too realistic treatment. He preferred bars set angle wise to square. Set anglewise they looked bigger, and also he thought they would resist pressure better. Some years ago a process for enamelling wrought-iron had been invented. Then there was a point as to how to design scrollwork, &c., in wrought-iron, which was to be fixed about 50 feet above the eye. The President then put the vote, which was carried by acclamation.

Mr. LONGDEN, in course of reply, said that he did not see Mr. Gardner present, though he had expected to see him. The swell-out joints, he said, had a beautiful effect, and were one of the highest kinds of enrichment got in the simplest manner. Much of the old ironwork in London was extremely valuable. There was certainly a valuable collection at South Kensington, but the gallery was too dark, and it could only be seen in silhouette. Notwithstanding the comments that had been passed he praised Mr. Sedding's work that was shown. As for protection of iron, he thought little of the various processes, as in a few years nothing more was heard of them, whereas if they had been of practical good they would have still been to the fore. The best protection was to soak ironwork at dull red heat in oil at the forge, and then paint it with good oil-paint—genuine oil-paint. All designing in ironwork should be doubled in size to show proper effect at 50 feet above the ground. High chancel-screens were not to be condemned because they appeared like webs. Moreover, they could be coloured and gilded, but it would be a great error to gild them entirely over.

JERPOINT ABBEY.

ON Tuesday there was an excursion of members of the Royal Society of Antiquaries of Ireland to Jerpoint Abbey, on the river Nore, co. Kilkenny, which was founded in the eleventh century for Cistercians by Donal MacGiolaupaudric, Prince of Ossory, and Felix O'Dullany, Bishop of Ossory. The ruins occupy an immense area. The following catalogue of the sepulchral monuments was compiled for the occasion by the Rev. Canon Hewson:—

Along the north side of the choir are ranged three niches, of which the moulding is for the most part broken away, but there are remains of the dog-tooth ornament. They contain four slabs, which have been in recent years raised upon rough masonry, after the fashion of altar tombs.

In the easternmost niche are two effigies side by side. The outer one is an ecclesiastic in alb, stole and chasuble. The chasuble is of ancient pattern like that of Bishop de Ledred's in St. Canice's, Kilkenny, not slit at the sides to admit of the hands being more easily brought forward, but gathered up at the elbows, and thence falling in ample folds. The feet, clad in socks without shoes or sandals, rest on a dog. The right

hand is uplifted, with the thumb and next two fingers extended, in the act of benediction. The left hand holds a pastoral staff, with its floriated part turned outwards, as is supposed, to indicate jurisdiction outside the abbey, *i.e.* the jurisdiction not of an abbot but of a bishop.

The inner figure in the same niche is also an ecclesiastic, holding with both hands a pastoral staff, of which the top is broken off. The feet rest on a bracket ornamented with conventional fruit and foliage of the style apparently of the latter part of the thirteenth century, and the whole figure rests on a mattress, ornamented all round in the same style. The vestments consist of an alb, with "apparel" at the lower part; a chasuble of decidedly later pattern than that of the other figure, though this by no means implies that the monument is of later date. It is slit up at the sides to admit of the free use of the hands, and is fitted to the figure. The girdle appears under the chasuble. On the maniple is a short fringe, and the head is covered with a cap. Neither of these slabs bear any inscription.

The next niche contains a coffin-shaped slab, with a short description rudely cut in incised Lombardic characters. The "HIC JACET" is quite plain, and so is the date "MCCC." The name of the deceased is injured, but it begins with "UI." There appears to be a second "HIC JACET," in memory of a second person. The centre of the slab is occupied by a human figure, cut in relief upon a sunk panel. The figure is equipped like a huntsman or light-armed warrior. A short skirt reaches to the middle of the thigh, a small bag or scrip hangs at the right side, by a strap over the left shoulder, and the right hand holds a spear. The prefix "UI" before the name indicates an Irish chieftain, and the dress and equipment is, no doubt, that of an Irish chieftain of the period. Over the head is a hole, about 5 inches square, cut through the slab.

The slab in the westernmost niche is also coffin-shaped, and is inscribed in memory of Edmond Walsh and Johana le Botiller. In the centre is a floriated cross, the arms of the Passion, and the Walsh arms—a chevron between three pheons reversed.

On the floor of the choir are two floor slabs. One near the south pier is inscribed to Peter, the son of James Butler, and Isabella Blanchfield, his wife, A.D. 1495. The inscription on the other floor slab is much worn, but with pains it might be read.

Under the tower is an altar-tomb inscribed on the top to Robert Walsh, who died A.D. 1501, and Catherine Poher his wife. In the middle of the slab is a floriated cross on a calvary and the Walsh arms, a chevron between three pheons reversed. On the south side of the tomb is a figure of the Blessed Virgin Mary, crowned, holding a lily in her hand, the Infant Saviour on her knee, and an inscription to Walter Brenagh (the Irish form of Walsh) and Catherine Butler, his wife.

On either side of the choir there are two chapels, four in all. The one adjoining the choir on the south has in the south-east corner an altar-tomb. On the top slab are two incised figures in chain armour, holding up with both hands very large cross-hilted swords. One figure has a visor closed, the other apparently none; both wear prick spurs. There is no inscription.

The ninth and last monument in this part of the church is an altar-tomb opposite the entrance to this chapel. On the top are two recumbent figures. The man in a loose civilian dress, with skirts or petticoats to his ankles; a harp is slung from his girdle by his right side; his right hand, pressed against his breast, holds something which may be a sceptre or staff, but it is broken off short, and the feet are clad in shoes. The upper part of the female figure by his side is broken off a little above the girdle and elbows. The sides of the tomb are ornamented with figures of apostles and saints in richly-moulded niches. One figure holds a saw; another a money-bag; another something like the five barley loaves; a fourth figure is winged and bears an infant in front. The inscription has been almost entirely knocked off. There remains but "Hic jacet Willmus," and fragments of three letters of the next word.

Near this last tomb, in the north-east corner of the cloisters, is an illustration of the legend of St. Christopher, similar to that seen at Kilcooley Abbey in the excursion of 1890.

In "Notitia Historica," by Nicholas Harris Nicolas, of the Inner Temple, bound up with "Memoirs of the Grace Family," by Sheffield Grace, London, 1823, are three long Latin epitaphs, in all thirty-four lines, or a full page, taken from Jerpoint Abbey. They are all in memory of members of the Grace family, viz. Sir Oliver Grace, of Legan, Carney and Ballylinch Castles, his wife Mary, one of the FitzGerald, of Decies, and their son Gerald, of Ballylinch, who died A.D. 1618, and his wife, Margaret Hartpole (of Shrule Castle, Queen's County), who died in the following year. None of these epitaphs appear to exist at Jerpoint now, except five lines, part of the epitaph to Mary Grace, *alias* FitzGerald. It is built into the west wall of the church. In this Mr. Nicolas has misread the date 1605 for 1515, and apparently a couple of words beside.

THE EXPLOSION AT WALTHAM ABBEY.

IN a letter to the *Times* the Rev. E. Mansel Townshend, M.A., curate, Waltham Abbey, offers the following remarks which deserve the consideration of the Government:—

In regard to the terrible disaster here on Monday, the 7th inst., it appears to me that sufficient attention has not been drawn, either at the inquest or in any report or article that has appeared, to the close proximity of the danger-houses of the nitro-glycerine works, and of the gun-cotton works, and of the nitro-glycerine magazine to a country town like Waltham Abbey, and to the men and lads at work close to these establishments in more or less dangerous workshops on Quinton Hill, every one of which—a dozen or so good-sized buildings—has, as any one can see, been battered by the recent catastrophe. Every one of these buildings contained quantities of either nitro-glycerine, gun-cotton, or cordite, and the more dangerous of them (incorporating houses, &c.) are closely packed together within about 50 yards of the great magazine which was blown up, containing, as it did, over a ton of nitro-glycerine, and which is authorised to contain about $2\frac{1}{2}$ tons. None of these workshops are protected from one another by earth-works or any other form of protection, nor by any safe distance from the magazine, which was fired by concussion (or by a trough connection) at a distance of 60 yards from the fortified washing-house, which first exploded, and 50 from the workshops or thereabouts, and exploded almost simultaneously, and yet above 100 men and boys are kept in these workshops and were there at the time.

The coroner acknowledged the narrowness of their escape, and the Government evidently recognised the extreme danger, as is shown by the thickness of the great walls of the magazine, washing and nitrating-houses, which were 10 feet thick, and are now two of them in ruins. Yet when a juror suggests that smaller quantities of nitro-glycerine might be stored by distribution, he is informed by Her Majesty's superintendent that there is "no room" to do this upon Quinton Hill, and that "an explosion in one house would communicate the explosion to another house." And this is at once accepted as a sufficient reply.

Now, this state of things is not the fault of Her Majesty's superintendent. That gentleman's reply, on the contrary, amounts to a statement of the gravest character, which affects others and not himself; and fear of censuring one whom we all hold, not only blameless, but greatly honoured and beloved in this place, should not have released the jury from their duty in calling attention to the fearful risk and the really criminal folly on the part of the Government in erecting workshops and a gun-cotton factory, with hundreds of workers engaged in them, under the lee and within 300 yards of a nitro-glycerine magazine and danger-houses, and the whole of these centres of mischief within 700 or 800 yards of a country town. Had the nitrating-house, containing half a ton of nitro-glycerine in a half-completed and dangerous state—*i.e.* liable to explode if heated above 80 deg. Fahr., or, by friction, if cooled below 50 deg. Fahr.—also exploded either by concussion, the falling of its roof, which actually occurred, or the fierce heat of the fire in the burning washing-house alongside raising the temperature, there is no knowing what would have happened to the town beyond what has occurred, for this great building and its substantial walls (albeit surrounding half a ton of nitro-glycerine) constituted our only (!) protection from the disaster on the other side of it. Surely when the Government attempt dangerous work of this kind it is their elementary and bounden duty to go two to four miles away from any town—many of their workers wisely live that distance off as it is—and to properly isolate, both by ample distance and lofty earthworks, their magazines and workshops from each other, instead of cramming them, without mutual protection, on to a dozen-acre field near a town and close to a villa, which they have ruined in value and safety as a home, without a penny of compensation.

Waltham people may be patient folk, who wish not to quarrel with that which brings them trade; but they have no right to be treated in this fashion, and something must be done to mend this trifling with terrific dangers. The powder magazine, three-quarters of a mile north of the town, contains probably ten times the explosive force of the nitro-glycerine exploded, in tons of gunpowder, by all accounts. This must be totally unnecessary, as it is not intended to be a permanent, but a temporary, store for the purposes of the factory, and to convert it into anything else is to add another danger to this much-endangered town, which ought not to be permitted and must be strenuously resisted.

Witley, Surrey, so long owned by Mr. Birket Foster, was sold by auction on Tuesday for 10,000*l.* The house is decorated with frescoes by J. D. Watson, a stained-glass window illustrative of the Seasons by Sir E. Burne-Jones, A.R.A., and works by Madox Brown and Rossetti.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

RICKMAN'S LETTERS ON THE ARCHITECTURE OF FRANCE AND ENGLAND.

(Continued from page 309.)

LETTER III.

AS the next subject in my comparison of the architecture of England and part of France, I intend, in the present paper, to submit to the Society* a rapid view of my ideas on the progress of architecture in England, from the occupation of the Romans to the period when the Italian style, again imported from Italy, drove out the execution, and for a time almost the study of the intermediate styles, of which so many excellent monuments are remaining.

I feel it necessary here to state, that for the sake of clearness I must assume some dates of buildings, which I am aware I cannot prove by documentary evidence, however well I may be convinced by analogy and a careful examination that the dates are true. But on the subject of documentary evidence, though I have the highest respect for it, yet it very often happens that the most important point, viz. whether the building now existing is the one really referred to in the document, must, after all, rather be collected from inference or analogy than be considered directly proved.

On that part of our architectural history which follows the departure of the Romans from Britain, and which precedes the Norman Conquest, there is of course great obscurity; but while in the days of Dr. Stukeley, Horace Walpole, &c., there appears to have been much too easy an admission of Saxon dates on the mere appearance of the semicircular arch, I think there has been of late perhaps too great a leaning the other way; and because we cannot directly prove that certain edifices are Saxon by documentary evidence, we have been induced too easily perhaps to consider that no Saxon buildings did exist, and have not given ourselves the trouble sufficiently to examine our earlier Norman works to see if they were not some of them entitled to be considered as erected before the Conquest.

I confess I have myself been heretofore of this class of doubters as to Saxon dates; but having in various parts found buildings which are not Norman, and which, from their peculiar construction, cannot well be considered either as modern or as of any intermediate style, I think they must be anterior and therefore entitled to be called Saxon.

I was much impressed by a conversation I had before my visit to France with an aged and worthy dean, who was speaking on the subject of Saxon edifices, with a full belief that they were numerous. He asked me if I had investigated those churches which existed in places where Domesday Book states that a church existed in King Edward's days, and I was obliged to confess I had not paid the systematic attention I ought to have done to this point, and I now wish to call the attention of the Society to the propriety of having a list made of such edifices, that they may be carefully examined.

Having premised thus much, I proceed to state what appears to me to have been the practical progress of architecture in England.

I think it is clear that nothing very good of Roman work ever existed in Britain; all the fragments of architecture which have been discovered, whether large or small, whether the tympanum of a temple as found at Bath, or small altars as found in many places, I believe they were all deficient either in composition or execution, or in both, and none that I know of have been better, if so good, as the debased work of the Emperor Diocletian in his palace at Spalato. With these debased examples we cannot expect that the inhabitants of Britain would (while harassed with continual intestine warfare) improve on the models left by the Romans.

It is not now to be ascertained whether any examples of the actual use of columns with an architrave incumbent were left by the Romans, but we have various examples of the plain arch with a pier; as a specimen the north gate of Lincoln, now used as it was many centuries ago for a gate, is perhaps the most perfect. The plain square pier and a semicircular arch I believe to have been imitated in the Saxon buildings, and this I find actually now a part of Brixworth Church, with a bond tier of what we call Roman bricks (*i.e.* flat tiles) carried through the work. This church has a curious window, in which is used a sort of pier or division, which is very rude, but has a resemblance to a Roman baluster. This baluster leads to one or two other churches, particularly the tower of Barton-on-the-Humber (old church), in Lincolnshire, and Earl's Barton, in

* The letters were addressed to the Society of Antiquaries.

Northamptonshire; these lead by other features to Barnack, St. Benet at Cambridge, a church in Oxford, Kirkdale, Loughton en le Morthen, in Yorkshire, and Repton, in Derbyshire, with a few other churches not yet sufficiently investigated, but altogether affording a series of work evidently not Norman, and in many cases having Norman work in such positions as to show that they must be more ancient than Norman.

I have heretofore met with many plain Norman-shaped arches between the nave and chancel of small churches, which appeared from the mode of construction to be relics of a more ancient edifice, and I am sorry to say that many of these, from the impression of their being only rude specimens of Norman, I have neglected properly to note or to examine whether they might not be Saxon. It is true that these sort of arches require careful investigation, for a plain arch on a plain pier continues all through the Norman style, and with a Pointed arch in the next style.

From this plain pier and arch the gradation is practically easy to the Norman style; the round arch remains, the impost remains, and a very little alteration improves the rude shaft of

very short, at Gloucester and Tewkesbury very long; it is also worked with plain as well as enriched capitals.

2. The square pier was reduced in size, but added to on the sides or the back and front, sometimes on all of them, by square sinks with shafts of various dimensions, and in a few instances with the sinks only without shafts.

3. In a very few instances, I believe, octagon piers will be found of Norman character.

The Norman enrichments of the capitals, mouldings and other parts are too well known to need description; but one Norman enrichment must be noticed, as it leads to a question upon which much has been written and little concluded. This enrichment is the series of panelling upon small piers, commonly called the intersecting arch. When once this ornament was used, the pointed arch was formed. Whoever also looks at a Norman groin, whether with or without ribs, must see an appearance of a pointed arch, and therefore I do not think it necessary to discuss the question of the introduction of the pointed arch here, as I know not that it can lead to any practical benefit.

AN ENGLISH DECORATED WINDOW.

Character of the Chapter House, York.

the little chapel at Kirkdale, in Yorkshire, into the ordinary Norman capital, and I suspect that this change was clearly developed about the year 1000, but this is one of the dates I cannot prove at present by documentary evidence.

The style which we designate as Norman is too well known to require much description. Evidently rude at first, it gradually softened its forms, multiplied its mouldings, and ultimately became in some examples almost gorgeous. The west front of Lincoln Cathedral is a fine example of the early and late Norman contrasted, the two side arches of the ancient front being evidently very early and the great west door very late.

Considering the Norman style as established, it is proper to notice how the plain square pier was altered.

1. It was made round with an enriched capital, sometimes of small projection and a round abacus or cap moulding, and sometimes with considerable projection and a square abacus. This pier we have in England of various heights—at Norwich

At whatever time this form was introduced, we find it curiously alternating with the semicircular one; they are often used together, and towards the end of the style and the beginning of the next we have Norman forms with Early English details, and Early English forms with Norman details, frequently occurring; and sometimes the forms and details are so mixed and jumbled as to make it very difficult to say to which style it belongs. But this is the great secret of the advance of architecture in England. It is so imperceptible in its progress that a series of examples of parts and ornaments and mouldings might be made out, each of them hardly differing from its predecessor, yet at every ten or twelve steps showing a decided alteration. It was by this gradual alteration that I conceive our beautiful Early English style was formed; this style, after struggling hard in the circular vestibule of the Temple Church, became in the eastern part a model of simplicity and beauty.

Then also appeared Bishop Poore's admirable edifice, Salisbury Cathedral, and that most valuable and numerous series of small churches which adorn almost every county in England.

It is well to notice that the churches of this date—viz. from about 1220 to 1300, or a little later—are remarkable not only for beauty and simplicity of design, but also for excellence of execution; seldom, indeed, is an Early English building seen without the best execution the material used is capable of.

How had this style been formed from the Norman?

1. The small window of the Norman style enlarged and with a pointed head became the simple but beautiful lancet window. The Norman double window, with a shaft between, became imitated in the double lancet, and afterwards in the double window with piercing between. As the Norman style had its more numerous assemblage of windows, so had the Early English. Each style its wheels; those of the former were small, those of the latter, much enlarged, became the magnificent transept windows of York and Lincoln.

2. The piers were altered principally by an alteration of their mouldings, but partly by a new and more elegant form. The round pier continued, the octagon pier also continued and increased in frequency in small buildings; but in larger ones the Norman square pier with shafts was changed into a bundle of shafts; four, eight, or sometimes more were used, and often a circular centre with four or more detached shafts set round it. These clusters of shafts were mostly united by the mouldings of the capitals, and part or the whole of the base mouldings, and sometimes by intermediate bands.

The deeply recessed arches of doors, &c., with shafts on the side, continued, but the shafts became of more importance, having sometimes in large doors a double tier of free shafts, one tier behind the other.

During this progress the mouldings were continually lightening and becoming more delicate, with intricate small hollows and small often repeated rounds, some plain and some filleted.

The rude and stiff Norman foliage and ornaments became more delicate and natural, and near the end of the style the sculpture of every kind was most exquisite. I need only instance the effigy of King John and those of some bishops in Worcester Cathedral, and that singularly elegant band of foliage in the side doorways of the choir screen of Lincoln. Amongst these enrichments we must not forget that simple ornament so profusely scattered in some of the best buildings of this style in England—the toothed ornament. All through the country is this enrichment seen, and it seems the regular gradation from the nail-head of the later Norman work to the square flower of the next style.

It is curious to remark that another peculiar characteristic of this style is a series of moulding for the bases of shafts, piers, &c., which is an imitation of the regular attic base of the Italians, consisting like that of two rounds and a hollow, with interposed fillets, but with this difference, that the Italian base is very rarely, if ever, worked so that it will hold water in the hollow, while the Early English base is almost always worked so that it will hold water, whether used within the building or in the open air, and its use is so general that wherever it and the toothed ornament are used together the style is most clearly made out.

About, or in some places perhaps before, the year 1300 another gradual change in the windows had taken place; instead of two or three lancets divided by a portion of stonework the thickness of the wall, and therefore keeping these lancets and any piercings between their heads distinct windows, there now appeared windows divided by real mullions, and the whole window surrounded by another general moulding of the nature of an architrave. The heads of these windows were filled with geometrical figures, mostly circles, and a new species of ornament began to be used, at first sparingly, but afterwards generally, not only in windows but in panelling; this was the insertion of a number of smaller arches with points, producing cuspidation or feathering, and thus introducing a new and elegant ornament into every portion of architectural composition, and its gradual progress from the first sort of trefoil heads, where all the mouldings assume the shape, to its later character of a mere enrichment on one only of a series of mouldings, is very curious.

Thus gradual had been the preparation of that beautiful style, which a few years after 1300 appeared pretty much confirmed in England, the Decorated English style. As transitions from the last style to this, two buildings are so pre-eminent as to require notice: one, the ruins of St. Mary's Abbey, York, is well known; but the other, the remains of the church at Newstead Abbey, has been comparatively little noticed for its architectural character: they are both so elegant as to deserve the closest examination and study, that their character may be properly known and appreciated. Beautiful as these edifices are, there seemed yet a graceful point wanting: these transition windows, and many of the early Decorated works, have tracery which is mostly circles, trefoils and

other geometrical figures, giving a certain appearance of stiffness to the lines of otherwise very fine windows; this geometrical tracery, though perhaps never entirely given up, was soon followed by tracery in which the lines are beautifully flowing, and window tracery seemed to have received its final polish; and of course with window tracery was included all heads of panelling, heads of buttresses, and other analogous enrichment.

The windows in this style continued to be enlarged till at length five, six, seven and eight lights were not uncommon, and in one instance (the east window of the cathedral at Carlisle) nine lights were employed. This last window is not only remarkable for its breadth and large size, but its composition is quite equal, if not superior, to any window of the style. We have very few wheel windows of this style.

A further alteration of piers took place in this style: the octagon pier still continued to appear in small churches, and in a very few places a round pier may be met with, but the capitals and bases show the alteration in the date, and another alteration took place in larger churches. In the Norman square pier with shafts the square faces were to the nave, the aisles, and to the arches; in the Early English style the shafts

AN ENGLISH PERPENDICULAR WINDOW.
Eaton Socon Church, Bedfordshire.

were set in a circular direction in large clustered piers, and now in the Decorated style the pier again became angular; but the angles of the square were set where the Norman faces were, and thus the pier becomes of a lozenge shape, and of these piers the front angle shaft to the nave sometimes runs up and becomes a groining shaft in the roof. In the Early English style the shafts, whether of piers, doors or niches, were mostly detached. Stability being required as well as lightness, these shafts were worked in the Decorated style as parts of the series of mouldings, and not detached, thus adding much to the strength of the building; and this was the case not only with piers, but in the mouldings of doors, niches and other analogous situations. The foliated capitals and other enrichments became very elaborate but with increasing boldness, and while they will bear close examination, they have their full effect at a distance. The toothed ornament disappears with the Early English style; but in the latter part of that style and the earlier part of the Decorated a round flower with three or four leaves closed on a ball, and well known by the name of the ball flower, became common, and was used in great profusion in some places. At Warmington, Northamptonshire, it is used

in Early English work with the toothed ornament, and at Ledbury in good Decorated work by itself in great profusion.

The toothed ornament was succeeded by the square flower we have mentioned before, which is used of various sizes in various situations with great effect.

The Decorated style had the shortest reign, and its good examples are not so numerous, perhaps, as either of the other styles; but there still remains enough to form a very efficient study of this most valuable style, the most difficult truly to imitate and equally difficult to describe in words. Although allowing of the introduction of profuse enrichment, it is not dependent thereon for its beauty, for the harmony of its proportions is such that some of the plainest specimens are as satisfactory as the most enriched.

Of this style the naves of York and Exeter cathedrals are fine examples; but there is one unmixed and very little mutilated example, which deserves to be better known than it is—this is the church of Heckington in Lincolnshire, on the road from Sleaford to Boston, and in its vicinity are several other fine examples of the style, varying in date and character, but mixed in some instances with the earlier and later styles.

I consider Gothic architecture in England at this time, about the end of Edward III.'s reign, to have reached its best point. But there came another alteration, and this I conceive had its origin in practical arrangements, dependent on what seemed an increasing desire to have very large and lofty windows and openings.

In many places the obtaining stone proper for the heads and mullions of very large windows was, no doubt, in the then state of roads and other communications a matter of some difficulty, and towards the end of the reign of Edward III. the new style began, and decidedly by the year 1400 it was established. The great distinction of this style from the last is the perpendicular lines of the windows and panelling and the introduction of one or more transoms, with trefoiled or cinquefoiled heads to the lights at the transom. It is true that many domestic and castellated windows had before been worked with a transom, more often plain, but in a very few instances (of which the very long two-light windows of the hall of the Palace at Wells may be mentioned) with arches and featherings; but these transoms now became general, and also a system of reducing the heads of windows and other places requiring tracery into small panels and producing ornament by a repetition of similar small panels over all parts of the enriched surface.

A much more general use of perpendicular and horizontal lines, either crossing each other or stopped by each other as each in turn became principal, was adopted, and in many rich buildings the panels often became niches with ornamented canopies, sometimes pointed, sometimes square.

One of the earliest and best specimens of this style is the north window, door and niches of Westminster Hall; the peculiarities of the style, its multiplied small buttresses to the niches, its shafts with capitals and bases partly round and partly octagon, its light pierced projecting canopies to the niches, its style of foliage, and, in short, every distinctive feature, is fully brought forward in this early example, and it may be examined by, and compared with, a very late example, Henry VII.'s Chapel, which is its near neighbour. It is true both these examples have had parts restored, but I believe both so restored that they may be compared with propriety, and their dates being clearly known—one in Richard II.'s reign, the other in that of Henry VIII., the completeness of the style at first will, I think, be fully proved.

Again, we find an alteration in piers and arch mouldings, and indeed in the mouldings of the style generally, by the introduction of large hollows into the suites of mouldings. The round pier is very seldom, if ever, used; but the octagon pier is as frequent as heretofore, its base and capital being altered. The large pier is still lozenge form, and much resembles the pier of the last style, but in many instances is not a square lozenge, but flattened between the arches, becoming of greater dimensions north and south than east and west, and in many instances there are no capitals, but the mouldings run round the arch and are stopped by some of the base lines of the pier, and frequently having bases to the rounds, though they have no capitals.

Another feature of this style is the introduction of the four-centred or Tudor arch; this appears to me to be the result of the practical effort to give as much apparent height as possible, and also of the wish to groin parts of buildings much flatter than could be done with the ordinary arch of two centres.

Although after the year 1500 a degree of debasement and want of proportion every now and then is evinced, yet the style could not be said properly to be debased till the end of the reign of Henry VIII. But early in the reign of Elizabeth true Gothic was mostly gone; Italian mouldings and the Italian orders began to be first mixed and then predominant; all the ornaments of the windows were gone, and the large square plain transomed window, sometimes flat and sometimes projecting as an oriel, became nearly universal. In the reign of James I. the Italian orders were considerably used; but of

what sort they were the tower of the Schools at Oxford sufficiently may show. I have met with one porch of a church, dated 1636 and a portion of wood screen-work dated 1660, both of which are fairly designed and executed in the Gothic style; but they are solitary instances, and on the restoration of Charles II. in 1660, Gothic architecture seems almost to have been forgotten; for till within a few years, with very little exception, the attempts at restoration have been very barbarous.

Having thus very slightly sketched my ideas of the very gradual practical progress of architecture in England, I propose in my next paper to take the same rapid view of the architecture of that part of France which has been before me in my late tour, in order to enable me afterwards more minutely to compare and contrast the several styles, as they appear to have been worked at the same periods, in England and in France.

I am aware that in this paper I have left out many peculiarities and distinguishing features of the different styles; but I trust I have said enough distinctly to mark the styles when in their purity, and also their singularly gradual progress through both the advance and decline of Gothic architecture, though it must be acknowledged that the decline was much more rapid than the advance.—I remain, thine truly,

THOMAS RICKMAN.

(To be continued.)

THE PRESTON TECHNICAL SCHOOL COMPETITION.

THE following correspondence has been sent to us for publication:—

To the Council of the Harris Institute, Preston.

22 Guildhall Street, Preston: May 2, 1894.

Gentlemen,—We, the undersigned, unsuccessful competing architects for the erection of the Harris Technical School, desire to draw the attention of the Harris Institute Council to the following points in connection with the competition, which appear to us, on the face of them, to constitute a breach of the terms under which we entered into the competition.

It would appear:—1. That the first clause of the instructions lays down "That the amount for shell of building from bottom of footings upwards, including supply of gas, water and low-pressure heating apparatus throughout the building, painting, finishing and architect's commission, must not exceed 8,500*l*." 2. That the Council have selected, and are about to carry out, a design which is to cost 13,000*l*. 3. That the costliness of the design—according to the statement of a member of the Council, Mr. Healey—has been cut down to come within this 13,000*l*.

We would desire to point out that under these circumstances those competitors whose designs were in accordance with the limit of cost laid down are thus placed in an unfair position by the acceptance of a design which, by the first clause of the instructions, ought to have been disqualified.

Having regard, therefore, to our rights as competitors, and with a view to ascertaining our position, we would respectfully request that the Council should satisfy us on the following points:—1. Whether the selected design is proposed to be carried out. 2. Whether the contract plans are in conformity with the designs as selected, or otherwise. 3. Whether the contract plans include any greater extent of building than the 8,500*l*. was stipulated to provide for, including architect's commission, and whether they include "supply of gas, water, low-pressure heating apparatus throughout the building, painting and finishing."—We are, gentlemen, respectfully yours,

JOSEPH V. HIBBERT (Preston).

G. SEDGER (London).

GARLICK & SYKES (Preston).

STONES & GRADWELL (Blackburn).

Harris Institute, Preston: May 9, 1894.

Dear Sir,—Your letter of the 2nd inst., addressed to the Council of the Harris Institute, signed by yourself and the other architects, was laid before the Council at their meeting to-day. The Council are unwilling to enter into any controversy upon the subject of the competitive plans for the new technical school. The plans were reported upon by a competent and independent assessor, and the selected plan was chosen by the building committee, and their choice was confirmed by the Council after a full consideration of his report. The Council consider that they have fairly and properly selected the best and most suitable plan, and that no competitor has any reason for complaint.

Will you please communicate this reply to the other gentlemen who have signed the letter.—I am, yours truly,

THOS. R. JOLLY, Secretary.

Mr. J. V. Hibbert, Guildhall Street.

VICTORIAN INSTITUTE OF ARCHITECTS.

AT the opening of the annual session of the Victorian Institute of Architects, Melbourne, Mr. A. E. Johnson gave an address. He stated that, having lately had an opportunity of travelling through Italy and many of the great centres of art, he was convinced that modern architects were worthily maintaining the traditions of the past, although in Australia they were hampered by want of access to the great art monuments which had inspired old-world architecture. The inferiority in our standard as compared with that of the old world was, he thought, due largely to the want of more thorough training in both the technical and artistic branches. The curriculum of the R.I.B.A. gave some idea of what the young architect had to go through in England before being "hall-marked." What was there done by paid specialists had to be done here by the senior members of the profession in their spare time. He understood that it was possible to secure at a small cost photographs of the splendid architectural collection brought together in the London Museums by the late Sir Gilbert Scott. There was, he feared, too great a tendency on the part of young architects to rush into business for themselves. The long training to which the continental architect had to devote himself before taking such a position even as that corresponding with clerk of works was in marked contrast to our practice, which it was to be feared very often brought the profession into contempt. A valuable contribution to this phase of the subject was a lecture recently given by Professor T. Roger Smith to the students of the London University, but particularly to those at the bottom rung of the ladder. The Professor took the ground that no natural gift could compensate for a lack of training in a great many of the essentials of the profession. As a proof of the desirability of adopting such methods of architectural culture as had been found successful at home, he would point to the great improvement noticeable in the architecture of the old country during the last thirty or forty years, and which could be gauged from the drawings of architectural subjects displayed in the London Royal Academy exhibitions, most of which displayed originality, good composition and beauty of detail in addition to splendid drawing. During a recent visit he was much struck with the improvement in London street architecture, especially in the dwelling-houses of such new squares as Kensington and Brompton, in suburban and country villas, and the many beautiful churches, all of which a like training would, he believed, alone enable us to emulate.

Gigantic Architecture.

SIR,—In the report of the Royal Academy banquet the Premier tells us in amusing language of his recent railway journey, and the inartistic objects of the earth, the sea and the heavens that came before his eyes as in a panorama, and I am afraid that the professional part of his audience felt little comfort or encouragement from the picture presented to them. Whether the architects who were there will feel bound to take warning by what was seen in the heavens at Wembley—a great, high tower built like that of Babylon, to a certain height and then deserted by its builders on finding that they spoke different languages—may be left with perfect equanimity to their good judgment when they are in the privacy of their studios. For myself the speech was suggestive of some practical considerations in architecture. We want an architecture up to date. London, with her immense population wanting larger and better and more sanitary habitations, is very probably on the eve of being incorporated by the London County Council, and her vast wealth will, in that event, be more justly apportioned for the general good. The little square mile of narrow lanes and tortuous passages and dark, overcrowded tenements will probably be, in time, unknown to their present pale and sickly inhabitants, having been intersected by noble avenues, with ample light and air—the birthright of every subject of the Queen. The science of the age is quite capable of dealing with this problem. The men who can take railway trains under the river Thames in perfect safety, who can build a Forth Bridge, standing firmly while the Tay Bridge was blown on a dark night into the river below, who can raise bodily an Egyptian temple thousands of tons weight and construct a reservoir where once it stood, and then plant the temple on a new foundation, we may be sure are the men to bring light into dark places, given the one thing needful—money. The provision of this, I suspect, is largely a part of the idea and purpose of the unification of London and of its complement—betterment, by which all will benefit, the rich

landlord, whose rents will not be less, though they may come from a smaller area in the present square mile, and the poor lodger in slums, who will find himself living in a new municipal palace.

Work like this is what the vast City estates—vast by increased value from the lapse of time rather than larger area—are, I think, wanted for, and depend upon it, sir, it has to be satisfied. Three powers combined will be all that is necessary—Parliament, the London County Council and the Ecclesiastical Commissioners. I forget, there is a fourth—the architects, those at least who have trained themselves by looking forward instead of, like mere archæologists, looking ever backwards, and are, consequently, incapable of originality.

Well, when, say in 1900 A.D., the little square mile has given up sufficient of its area for ample thoroughfares, the new municipal buildings will show their qualities. "New lamps for old," light and air will be secured by piers half the area and double the strength of those at present customary, by girders of double the present bearings, a general construction in storeys, double the present number, every or every other storey set back about 10 feet, so as to do away with the present gloomy character of the buildings of the City, and enable sky-lights to be obtained where required. This would be an improved method of meeting the clause in the Act that limits the height of buildings in proportion to the width of the street in which it stands, while the area and rents gained by the extra storeys will repay, or largely repay, the money spent on the improved thoroughfares and open spaces. Iron, steel, glass and terra-cotta will largely supplant the old brick and stone in this new municipal architecture—this architecture up to date.—Yours truly,

HERMES.

GENERAL.

Victoria Park, Macclesfield, the gift of Mr. F. D. Brocklehurst, J.P., Harehill, has just been opened. The grounds are very extensive and charmingly situated. The gift represents about 10,000*l.*, and some hundreds have been expended in laying out the park.

The Prince of Wales on Saturday last inaugurated the summer and autumn season of the Imperial Institute, by formally opening the exhibition of artistic and decorative pottery and china and glass which has been organised by the executive council.

A Hampshire Landscape, The Firs, painted by Mr. David Murray, A.R.A., has recently been acquired by the Glasgow Corporation for the art gallery.

Blackfriars Bridge was partially closed for repaving on Wednesday, space having been left for two lines of traffic while the work is being carried out.

The German Emperor has promised to contribute 500*l.* annually for some years to come, for the building of a state theatre at Bromberg.

A Portrait painted by Mr. Joseph Henderson, R.S.W., of ex-Lord Provost Sir John Muir, Bart., has just been hung in the Glasgow Corporation Art Gallery.

Mr. J. Donovan Adam, R.S.A., of Edinburgh, lately sent to the Salon des Champ Elysées a painting entitled *Before the Setting of the Sun*, which the French Minister of Fine Arts has, on behalf of the State, decided to purchase.

The Outdoor Sketching Season of the Dublin Sketching Club for 1894 has just been inaugurated, when the members of the club met at Dalkey on their first excursion. The president, Mr. John L. Robinson, R.H.A., M.R.I.A., hospitably entertained the members and friends at his residence, Rathruadh, Glengary.

The Members of the Lancashire and Cheshire branch of the Incorporated Association of Municipal and County Engineers and Surveyors have just paid a visit to Chester. A paper on "Steam Road-rolling" was read by Mr. Allan Greenwell, surveyor to the Frome rural sanitary and highway authority; and Mr. Albert Wollheim, C.E., read a paper on "The Eaton and Eccleston Sewage Precipitation Works."

It is stated that what is probably the largest piece of cut glass ever made in America is at present on exhibition in New York city. It weighed 70 lbs. before it was decorated, and lost about 20 lbs. in the cutting.

A New Organ, presented to the Dean and Chapter of Peterborough Cathedral, has been dedicated. The organ cost 4,400*l.*, the builders being Messrs. Hill & Son. A considerable number of stops which formed part of the old organ, built early in the century by Aller, of London, have been incorporated in the new instrument.

During a Thunderstorm at Ashby-de-la-Zouch one of the pinnacles of the square tower of the parish church was struck by lightning and several feet of the carved stonework demolished. The current also tore up a portion of the plaster and brickwork forming the roof of the tower.

The Architect.

THE WEEK.

THE defeat of the French Ministry, we suppose, means the loss of office by M. SPULLER, the Minister of Fine Arts. It was only on Friday last he was present at the opening meeting of the congress got up by the Union Centrale des Arts Décoratifs, in order to consider what measures were best adapted to promote the development of industrial art in France. M. SPULLER delivered such an address on the relation between art and industry as every French deputy is able to supply at a moment's notice. In conclusion he told the Council of the Union that if they ever were in want of money they were not to hesitate about asking him for it. This of course raised expectations of a liberality which was novel to the Union, for it is kept up by lotteries and donations; but M. SPULLER added, "It is probable that I shall not give you any money, but your visit may be an announcement to my successor, who may be better able to supply you." At the time the Minister could not have anticipated the approaching collapse. The Union has not succeeded in establishing a museum in Paris, but it is considered that something might be done if the provincial societies would be more loyal in their co-operation.

THE fourteenth congress of the Sanitary Institute will be held in Liverpool from September 24 to 29. Three general addresses and lectures will be delivered. Sectional meetings, dealing with (1) sanitary science and preventive medicine, (2) engineering and architecture, (3) chemistry, meteorology and geology, will be presided over by Dr. E. KLEIN, M.D., F.R.S., Mr. G. F. DEACON, C.E., and Dr. THOMAS STEVENSON, M.D., F.R.C.P. Special conferences on the sanitation of the passenger and mercantile marine service, on medical officers of health, municipal and county engineers, sanitary inspectors, and domestic hygiene will also be held. In connection with the congress, an exhibition of sanitary apparatus and appliances and articles of domestic use and economy will be held in the Drill Hall, Upper Warwick Street. Excursions to places of interest in connection with sanitation will be arranged for members attending the congress. The local arrangements are in the hands of an influential local committee, presided over by the Lord Mayor of Liverpool, with Mr. H. PERCY BOULNOIS, the city engineer, and Dr. E. W. HOPE, M.D., medical officer of health, as honorary secretaries. Over one hundred sanitary authorities, including several County Councils, have already appointed delegates to the congress, and as there are 1,500 members and associates in the Institute, there will probably be a large attendance this year.

SOME remarkable churches were visited by the members of the Clifton Antiquarian Club during their excursion in Monmouthshire last week. One was at Matherne, and marks the burial-place of St. TEWDRIC, the hermit king of Glamorgan, who was slain in a battle against the Pagan Saxons in the sixth century. The church consists of a massive western tower, with nave, north and south aisles, south porch and a long chancel. Originally it was an early thirteenth-century building, to which period the arcades of four bays still belong, as well as the chancel, though later interpolations have been since inserted. The tower and aisles were rebuilt in the fifteenth century. FRANCIS GODWIN, who was bishop of Llandaff from 1601 to 1617, gives the following account of the Welsh king, who was revered as a martyr:—"The manor of Mathern, where there is now a palace, was given to the bishops of Llandaff by MAURICE, king of Glamorgan, about the year 560, on the following occasion. His father, St. THEODRIC, as he is usually called, having resigned his crown to his son, embraced the life of a hermit. The Saxons, invading the country, THEODRIC was reluctantly called from his hermitage

to take the command of the army. He defeated them near Tintern, upon the Wye. Being mortally wounded in the engagement, he precipitated his return that he might die among his friends, and desired his son to erect a church and bury him on the spot where he breathed his last. He had scarcely proceeded five miles when he expired, at a place near the conflux of the Wye and the Severn; hence, according to his desire, a small chapel being erected, his body was placed in a stone coffin. As I was giving orders to repair this coffin, which was either broken by chance, or decayed by age, I discovered his bones, not in the smallest degree changed, though after a period of a thousand years, the skull retaining the aperture of a large wound, which appeared as if it had been recently inflicted. MAURICE gave the contiguous estate to the Church, and assigned to the place the name of Merthyr Tewdric, or the Martyrdom of THEODORICK, who, because he perished in battle against the enemies of the Christian name, is esteemed a martyr." The bishops of Llandaff resided at Matherne from 1408 to 1706. The palace was commenced by JOHN DE LA ZOUCH, A.D. 1408, and was completed by MILES SALLEY, A.D. 1504. The stone coffin mentioned by Dr. GODWIN was again revealed during the restoration of the chancel in 1881.

THE sculptured panels for St. George's Hall, Liverpool, have been completed and fixed by Mr. STIRLING LEE. The commission was given to the sculptor by the Corporation. When two of the panels were placed in position an outcry was raised about their unsuitability, and an effort was made to escape from the responsibility for the remaining four. Mr. Alderman RATHBONE, who manfully upheld the cause of the artist, then offered to have the series completed, but stipulated that the panels were not to be disturbed for at least two years after they had been erected. Time has had a sobering effect on the opposition, and the new panels are not likely to be subjected to the sort of criticism which their predecessors had to sustain. The following are the subjects of the series:—1. Joy follows the growth of Justice, led by Conscience, directed by Wisdom. 2. Justice, in her purity, refuses to be diverted from the straight path by Wealth or Fame. 3. Justice, having attained maturity, upholds the World, supported by Knowledge and Right. 4. Justice, able to stand alone, administers by the sword. 5. Justice is relieved of her sword by Virtue, and of her scales by Concord. 6. Justice receives the kiss of Righteousness and the crown of Immortality. It will be seen that the panels relate to the use of St. George's Hall as a Court of Justice. The date for unveiling them has yet to be arranged.

OF late years exhibitors have not derived much profit out of international exhibitions. In the future they must not expect compensation for the past. The Royal Commissioners of the Chicago Exhibition suggest that unwelcome circumstance when they announce that individual exhibitors must subordinate themselves for the sake of producing general effect. In other words, exhibitions are to become contests between nations, and exhibitors are to consider themselves as mere rank and file that must expect to be sacrificed, and if they survive have little chance of glory or other reward. If they are not willing to sink their individuality or fight in masses, "they must be content to see public attention attracted by the better organisation of their rivals." It is objected that at Chicago the general effect produced by the British section was not equal to some others. The report does not, however, indicate in any way whether foreigners who made sacrifices for their own and their country's good derived benefit from the Chicago Exhibition. As far as we can judge, the only gainers were the Americans. They were able to realise what was most desired in Europe without the trouble of crossing the Atlantic, and they have since taken advantage of the information by entering into competition with the producers of the finest classes of goods in continental cities. To an economist it is gratifying to see the New World fighting the Old World, but a plain man will think it hard that the latter should be compelled to instruct rivals in commercial strategy without receiving any payment for the lessons.

DANTE GABRIEL ROSSETTI.*

THE memoir of DANTE ROSSETTI is described as "one of the tributes of an old friend," for Mr. STEPHENS has often served as an interpreter between his brother pre-Raphaelites and the public. It is needless to say that he possesses the qualifications for a service of that nature. He was associated with the painter during eventful years, and aided in developing his theory of art, and afterwards, as a writer on art, Mr. STEPHENS was acquainted with the history of all ROSSETTI's pictures, a subject that has its obscurities. This dual relation is exhibited in the memoir. Mr. STEPHENS writes as an old friend, but while offering his tribute, he does not wish it to be interpreted as evidence of his belief that ROSSETTI was the greatest of modern painters. Indeed, he admits that a man who was less munificently endowed with gifts by nature would have been more successful as an artist, or, to use his own words, "While I wonder at his achievements, and know how great were the powers he employed, I cannot help thinking that a less complex nature would have done still more than, so far as time and space allow, these pages have to report of and illustrate." The lines suggest one of the characteristics of the book. Mr. STEPHENS shows the progress of a great genius in overcoming obstacles, but he also reveals in the kindest manner how some of the most perplexing were not external. ROSSETTI would not object to that sort of presentation. He was too shrewd a man—too fond of analysing the motive-powers of life—to suppose that he was always a heroic painter. When he wrote to one of his supporters about his difficulty in completing a commission, and might have little to show, he said, "It may be otherwise, however; there is no knowing in such a lottery as painting, where all things have a chance against one—weather, stomach, temper, model, paint, patience, self-esteem, self-abhorrence, and the Devil into the bargain," he was confessing that he was only a fallible genius after all.

DANTE ROSSETTI was a child of his time, and he could not be free from its weaknesses. He was born in 1828. His father belonged to Vasto d'Ammonio, in the Abruzzi, and was an official in the Naples Museum when one of the periodical revolutions broke out. To escape the royal vengeance he fled, and in 1825 he found a refuge in London. He became a teacher, and in 1831 obtained the professorship of Italian in King's College. Excellent as is that institution, it insists on the orthodoxy of its humblest officials, and ROSSETTI could not have been accepted to explain the rules of grammar unless he had made a sacrifice of his early belief. A man who goes through that sort of reform generally strives to become over-convincing of himself and others, and Mr. STEPHENS suggests a good deal when he says the Professor "looked like an old and somewhat imperative prophet, and his voice had a slightly rigorous ring in speaking to his sons and their visitors." Poor DANTE is described as on that occasion "leaning his elbows upon the table and holding his face between both hands, so that the long curling masses of his dark brown hair fell forward, his attenuated features sharply outlined by the candle's light." He received his first teaching from his mother, "an accomplished and devoted matron, whose affection was, even to his latest days, ceaselessly acknowledged by her son." Then he went to a private school, and afterwards to King's College.

In 1843 he began to draw, and apparently as soon as he could use a pencil he attempted the illustration of his own stories. He joined CARYS Academy, and by 1846 he was sufficiently accomplished to be received as a student of the Academy. A reputation for poetry and sketching chivalric and satiric subjects had preceded him. He was not made of the ductile stuff which is satisfactory to Visitors. Revolution was in the air, and affected art as well as politics. PUGIN had with all his energy exposed the shams of architecture; CARLYLE had warned the world of its doom because of its inaccuracy; the very ballad-singers in the streets were announcing that a good time was coming. The competition of the cartoons for the frescoes of the Houses of Parliament had brought novel and stereotyped treatment into opposition. Among all the attempts the

strangest was MADOX BROWN's, and when he by a few later works demonstrated that he was not strange by accident, but through conviction, young ROSSETTI, who had attained the ripe age of twenty, offered to become his disciple, but in such glowing terms of admiration that BROWN imagined they were only a new form of the sarcasm to which he was accustomed, and sought his votary in order to cudgel him. But he was moved by the lad's genuine faith, and immediately offered to become his teacher and without fees. The first exercises were a severe test to one who could write and illustrate his own poetry. It appears ROSSETTI was set to copy pickle-jars and other inspiring examples of still life. Earnest as was MADOX BROWN, he was not, perhaps, the most suitable hand to give bias to ROSSETTI's instincts, but fortunately there was another influence. Mr. STEPHENS, with his competency to decide on this subject, says:—"There can be no doubt whatever that to BROWN's guidance and example we owe the better part of ROSSETTI as a painter *per se*, although his will to study with tenacity, and thus command success, might have been stiffened by the encouragement and example of Mr. HOLMAN HUNT, apart from which I fear the latter-named student was not the fittest guide for a genius like ROSSETTI, who very soon departed from the uncompromising principles of the indomitable friend who had never been, even for an hour, his model on art. Rather had the brilliant and happy power of MILLAIS, one of the finest painters of the age, and a born artist, been as light before the subject of these pages."

In 1848 ROSSETTI became co-tenant with Mr. HOLMAN HUNT of a "large gaunt chamber" in Cleveland Street, Fitzroy Square. Before the year was over the two young artists had united with J. E. MILLAIS, T. WOOLNER, J. COLLINSON, F. G. STEPHENS and W. M. ROSSETTI in forming a League of Sincerity. To them may be joined W. H. DEVERELL, although he was not formally elected. According to Mr. HOLMAN HUNT, the inspiration for the League was derived from engravings after the frescoes in the Pisan Campo Santo. Mr. STEPHENS says:—"There was no intention of following, much less copying, the modes and moods of the artists who preceded RAPHAEL, nor of repeating anything which had been attained in art's service since the days of that Prince of Painters. Each friend was to work in his own way, and if an edifying use could be made of the subject, so much the better, yet nothing like a didactic, religious or moral purpose was insisted on by any brother." In about a year the aims of the League were widened, and it was resolved to elevate literature by establishing a publication called the *Germ*. Only four numbers appeared. Copies are coveted by collectors, but we are afraid it is not from admiration for the essays or poems.

About the sincerity of the members there could be no question. The League bore no correspondence to modern literary and artistic "rings," that are organised mainly to attain commercial success by efforts which are supposed to be disinterested. Few could understand what the Brotherhood were trying to do, but everybody was at least convinced that the young artists had resolved to demonstrate that the taste of the public in England was towards unworthy objects. People were not likely to be gratified by the discovery. In their turn they mocked the reformers, and of course did not appreciate the works of the League. ROSSETTI was fortunately able to sell his first picture, *The Girlhood of Mary, Virgin*, for 80*l.* to a lady, but for the *Ecce Ancilla Domini*, an exquisite and original interpretation of the Annunciation, he asked 20*l.* less, and although it was exhibited there was no purchaser attracted. It remained with the artist for three years, and then it was bought by a man who had not seen it, but was of a speculative turn. In 1886 the picture was purchased for the National Gallery at 840*l.*, or fourteen times the original price.

The two pictures merit to be accepted as thoroughly representative of ROSSETTI's style. By practice his technique was improved, and he gained the power of more clearly expressing his thought, but his idea of art appears to us as marked in the two pictures, and especially in the second, *The Annunciation*, as in any of his more matured works. That idea, which he held in common with the other pre-Raphaelites, was the expression of complex emotions. "There is no art," says SHAKESPEARE,

* *The Portfolio Monographs on Artistic Subjects: Dante Gabriel Rossetti*. By F. G. Stephens. London: Seeley & Co., Limited.

"to find the mind's construction in the face," and a great many English painters have accepted the words as authoritative. The Greeks also seemed to have believed in a similar principle. The pre-Raphaelites, on the contrary, considered the face was a revealer of emotions. In their eagerness to be sincere, they sometimes went to lengths which the discipline of good manners or self-respect would not tolerate in the men and women who were depicted. It is only necessary to glance at some of the pictures which are now in the Guildhall Gallery for evidence of this fact. As a consequence of its being less expressive, the figure was often carelessly modelled, or posed in a way that was a defiance of anatomical restrictions. ROSSETTI, in course of time, showed a preference for heads alone, or for busts and half-lengths at the most. So accustomed are admirers to his ways, we doubt if any of them will observe at first sight any deficiency in the reproduction of the unfinished *Our Lady of Pity*, which occupies one of Mr. STEPHENS's pages. As the head and hands are nearly completed, it seems of little consequence that the figure is indicated most indefinitely.

As faces, and especially those of women, were of so much importance in ROSSETTI's eyes, it is no wonder when he discovered one that corresponded with his desires, or to which his desires could be accommodated, he made many repetitions of it. We might go so far as to say that the works of ROSSETTI could be most clearly classified according to the faces by which he was captivated from time to time rather than by dates or subjects. The faces did not always correspond with the ordinary standard of what was beautiful. ROSSETTI, as in his *Lilith*, could produce a head and bust which would bear to be hung in a gallery with a copy of the *Venus of Melos*, and which everybody could appreciate. What he preferred, however, was something that would be thought mysterious, like DA VINCI's *Mona Lisa*. The two artists believed they alone understood what the French call the Eternal Feminine. DA VINCI, we suppose, imagined there was "une passion sérieuse, noble, éternelle," as CONSTANTIN says, operating somewhere behind the eyes of LISA DEL GIOCONDO, when probably she was speculating whether all the time the painter was spending over the portrait was to be charged, and at what rate. When ROSSETTI imagined his model was looking before and after simultaneously—or, as he expressed it, "the shadowed eyes remember and foresee"—she may have been thinking about somebody's new bonnet, or whether her cloak was likely to suffer permanently from the last shower. The mysterious beings he painted were not always remarkably intellectual, or apprehensive of "the awful shadow of some unseen power." It must be allowed, however, that ROSSETTI's heads are impressive and not easily forgotten. A collection of them may be disappointing or painful, but that might be said of several of DA VINCI's smiling half-figures, like the *Mona Lisa* or the *Baptist*, if they existed and could be brought together in a gallery.

In compositions where several figures were introduced ROSSETTI was not always successful. He seemed to care little about subordination, and as all the figures appear to have equal importance, which in an ethical sense may have been right, the incident illustrated does not become manifest. It was for that reason, we suppose, he was rarely employed by architects. His mysticism and the unworldly character of so many of his figures qualified him for church decoration; but works which constantly stand in need of an interpreter are not adapted for town or country congregations. He was more fortunate in his designs for stained-glass. On that subject Mr. STEPHENS writes as follows:—

From the first he mastered the facts that, unlike pictures proper, which are seen by reflected light, paintings on glass, being transparent, are seen by transmitted light, and do not permit the use of modelling in light and shade, intended to give a false appearance of relief to that which ought to be of the nature of a mosaic in transparent media, with shadows, not modelled to anything like naturalistic or imitative results. Knowledge of this principle lies at the root of design in this application, and yet so dense was the ignorance of art then prevailing among antiquaries and *cognoscenti* that Mr. C. Winston, a great authority on the history of glass-painting, and a first-rate copyist of ancient windows, refused to accept this rudimentary canon of the subject, and sanctioned those illogical and inartistic transparencies which, vilely designed and childishly-executed in the picture glass-works at Munich, offend the eyes of critics in St. Paul's and Glasgow Cathedrals. Greatly to Rossetti's influence, though not perhaps to his

initiative (about which I am not certain), is due the successful and brilliant revival of art in glass, which has flourished chiefly by means of Messrs. F. M. Brown, W. Morris, Sir E. Burne-Jones, and a few other competent artists and manufacturers, by which the whole art and practice of *vitræx* have been revolutionised.

ROSSETTI's colour sense was exemplified in other productions besides stained-glass and pictures. It was exemplified also in his poetry. As Mr. STEPHENS says, "These poems, and especially the sonnets, are the outcome of a genius essentially pictorial, that is to say, a mind which saw everything, from the rose and ivory of a woman's carnations to the sullen splendour of a sunset, with the eyes of a painter revelling in colour, enraptured by the grace of a perfect curve, and capable of exquisite and sympathetic research when human pathetic expression was in view." So much versatility or power to treat various forms of art as if they were all one to a man who had the insight to perceive their relations, is Italian. The qualities of the race were no less manifest in ROSSETTI's skill in affairs with which mysticism and romance might seem to have no connection. Mr. STEPHENS refers to the artist's "business capacity, in which, as a bargain maker, cash receiver and negotiator in general, he, to the wonder of his artistic and poetry-loving friends, shone greatly. Of his powers in these respects, bankers, lawyers, merchants and everybody whose wisdom in cash and commerce was unchallengeable, spoke with unreserved admiration, not to say surprise."

It is not often so remarkable a combination of talents is found in any country or time. ROSSETTI was phenomenal, and it is an advantage that so careful and accurate an account of his life and works has been brought within the reach of the humblest students of art.

EDINBURGH ARCHITECTURAL ASSOCIATION.

THE annual general meeting of the Edinburgh Architectural Association was held in the Royal Institution, Princes Street, on the 16th inst., Mr. W. W. Robertson presiding. The treasurer's statement showed a deficiency of 42*l.* 4*s.* 5*d.* at the close of the session, caused, it was explained, by an increase in the expenditure, the income being practically the same as last year. Mr. W. W. Robertson was elected president for the ensuing year, Dr. Rowand Anderson and Mr. Thomas Ross vice-presidents, and Mr. T. Fairbairn secretary.

The President, in his address, discussed one or two subjects of interest to the Association and the city. He recalled the deputation to the Edinburgh Town Council, to urge upon that body that the best architectural skill available should be conjoined with that of the engineer who might be invited to design the new North Bridge, and that in respect of the buildings at the north end of the bridge which the railway company propose to rebuild, the existing restrictions as to height should be maintained entire and undiminished. From their reception by the Council, and from what was said at the time and shortly afterwards, they fondly hoped that they had so impressed the members with their views as to go far to secure their adoption. What might be the action of the Council as to the designing of a new bridge they did not yet know; but as to the Council's action on the other point, he confessed to a feeling of disappointment. The present height of the higher portions of those buildings was about 55 feet, and the railway company proposed to take power to go 95 feet above the street to the ceiling of the highest inhabited storey. What the city had agreed to was a clause providing that the height should not exceed 80 feet to the wall-head without the consent of the Corporation. Now the difference between 80 feet to the wall-head with a storey above in a mansard roof, and 95 feet to the ceiling of the highest inhabited storey was very much the difference between Tweedledum and Tweedledee, and the concession secured by the town, which seemed little enough at first sight, was found on examination to be nearly altogether illusory. The building would still be raised about 50 feet, and would still overtop and most prejudicially affect everything in its vicinity. From Sir Walter Scott's Monument and Princes Street to the west it would wipe out a great part of the view of the Calton Hill. Viewed from the Calton Hill in the vicinity of the Nelson Monument, whence one of the finest views of Edinburgh was obtained, the effect of such a building would be simply disastrous. It would block the view from the Castle Hill on the left to the Scott Monument on the right, and shut out the view of the valley as completely as if a huge shutter were drawn up. It was not merely the loss of the view of the valley, with its deep hollow and refreshing greenery contrasting so beautifully with the buildings of the old and new town on either side, that they should have to lament. The building would shut out of view the whole vertical portion of the outlin

of the Castle rock, and thus not only destroy entirely its characteristic appearance, but deprive it of half its apparent height. From nearer points of view—from the south looking down the North Bridge, and viewing it as part of the group surrounding the register office crossing, the effect was equally disastrous. He gathered from the *Scotsman* columns that one town councillor gave it as his opinion that the committee of the House of Lords would not be likely to interfere with the Bill because the building would shut off the view of Princes Street Gardens which a few people might have from the Calton Hill. There must have been some subtle humour in the manner of the remark, because it was received with laughter, which, as far as his judgment went, could hardly be provoked by the matter of it. It hardly needed to be pointed out that the same wise remark might be made of any one of these features of loveliness which, taken together, constituted the priceless dower of beauty with which nature more than art had endowed their beloved city, and which made her "beautiful for situation, the joy of the whole earth." Surely the beauty of Edinburgh was beyond price; and if her sons had that deep appreciation and affection for her which they ought, they would value those who tenderly sought to preserve it, and would say from their hearts, "Let them prosper that love thee." On the other hand, he doubted not that a second Scott would arise to pour "a minstrel's malison" on "the dull destroyer's head" who bartered this birthright for a mess of pottage, and celebrated the bargain with a jest. For the actual action of the Town Council he could find many excuses. In their complex negotiations with the railway company they had to give and take, and it was a misfortune from their point of view that although doubtless they would have preferred to insist on this building being kept low, there were other points to which they attached greater importance, and to secure these they gave the point away. The Bill had still to pass the House of Commons, and they would fain hope against hope that some amendment might be made there. But there was little hope of this. The natural guardians of the amenity of the town had said their last word, and entered into a treaty with its assailants. The public showed no sign of interest. The public never did realise the effect of a change such as this till it was made and beyond repair. Then there would be a torrent of letters in the newspapers, as they continually saw about much smaller matters, if the papers would print them. A singular contrast to the apathy of the public on what they might call the larger questions of amenity was the feverish outburst of correspondence on the great question of projecting signs. Not that the subject was without its interest. In the olden time, before the simple expedient of numbering the houses in a street had been adopted, the only way for one particular place to assert its individuality and make it easy for travellers, messengers and others to identify it was to adopt some visible sign, which constituted part of its address, and was used both in dating and directing correspondence. How largely this practice had entered into and given local colour to literature, from the days when Chaucer's pilgrims gathered at the sign of the Tabard, or these latter days when Ben Jonson and his compeers assembled at the Mermaid, down to the writings of Scott, Dickens and Thackeray, they need not say. In busy places where competition ran high great efforts were made to excel in this matter of signs, and they grew in size and importance, and the greatest ingenuity was displayed in devising something new and striking. At last the evils connected with this became so serious that in 1762 an Act of Parliament ordered them all to be removed, or if retained to be placed against the fronts of the houses. It seemed there had been a considerable increase in the number of such signs in the city, and the city fathers had resolved to put in force the powers which they had had for the last fifteen years, and had ordered a wholesale removal. The powers of the Act, he contended, however, were so excessive they never could be intended to be exercised.

On the motion of Mr. James Bruce, W.S., seconded by Mr. Thomas Bonar, a vote of thanks was awarded to the President.

On Saturday the members of the Association visited the old castle of Dalzell, the seat of Lord Hamilton. The castle is situated in a romantic situation on the steep bank of a brawling stream, which runs in a deep and rocky gorge, winding its way round the east and south sides of the old building. In ancient times the other two sides were defended by curtain walls and a moat. The situation of the castle was doubtless selected because of the security its position afforded, and not from the charming nature of the scenery which captivated the eye of William Cobbett, who visited Dalzell in 1832. Describing the venerable and massive castle, and the wild rocky glen from which it rises, contrasted with the majestic flow of the Clyde, which runs near by, he says it is the place at which, if he were compelled to reside in Scotland, he would choose to live. The original keep is a characteristic example of its kind, and is still entire, and forms a most charming part of the house. It probably dates from the fifteenth century, and was doubtless built by Dalzell of that ilk, a family in whose possession the barony had been for several

generations till 1647, when it was acquired by James Hamilton of Boggs, ancestor of the present proprietor. He made extensive additions to the castle, and his arms and those of his wife, Jean Henderson (of the Fordell family), are still to be seen on the house, with the date 1649. The present Lord Hamilton greatly added to the structure about 1847. The late Mr. Billings, the author of the well-known book "The Baronial Antiquities of Scotland," was the architect employed. Mr. Billings resided at Dalzell during the time the work was in progress, and a great deal of the rich carving and the elaborate plaster ceilings was wrought with his own hands. The party next walked to Jerviston House, about a mile distant from Dalzell. This is an ancient seat of the Baillie family, and overlooks the Clyde not far from Motherwell. It is probably a house of the end of the sixteenth century, and is a good example of the kind of houses erected at a time when comfort and convenience were the principal objects studied.

THE INFLUENCE OF THE MYLNE ON THE ARCHITECTURE OF EDINBURGH.*

IN the case of the family of Mylne we notice this interesting peculiarity, that the name of the builder can be shown to be connected with a vast number of structures throughout a long period of time. John Mylne became master mason to James III. Abbot Alexander Mylne was master of works to Dunkeld Bridge, and afterwards one of James V.'s principal advisers on architectural matters. In other respects, also, he was a considerable personage, and played an important part in the history of Scotland. We are, however, on the present occasion considering the influence of the family of Mylne on the architecture of Edinburgh, especially during the seventeenth and eighteenth centuries.

John Mylne of Perth first came to the fair capital of Scotland, of such high renown in ancient story, in the year of grace 1616. His main object was, at the request of the town council, to complete the ornamental statue of King James VI., ordered to be placed on the Netherbow Port in honour of his majesty's expected visit to his native land, which took place in the following year. This decorative work was carried out in an elaborate manner, since "sixty buiks of gold" were secured at 80*l*. Scots; and Henry Mylne, goldsmith, was employed to make the sceptre of St. Andrew and St. George with the order of the thistle. Full particulars will be found on page 106 of the "King's Master Masons." When once a successful start had been made, other employment quickly came to hand. John Mylne was appointed to erect a new basement structure for the city cross, and on March 25, 1617, "the croce of Edinburgh was put upon the new seat." He also carried out works at the West Port, and was paid 10*l*. "for making the scaffold that the provost, baillies and counsall stood on at his majestie's entry." On June 4 he was made a burghess.

After taking part in the erection of the church at Falkland, the new steeple of the Tolbooth at Aberdeen, the sun-dial and some portions of Drummond Castle, John Mylne is summoned to Edinburgh to construct a water pond at Holyrood for Charles I., and soon afterwards is appointed king's principal master mason under writ of the Privy Seal. Amongst other works executed for the king, he was employed to make the celebrated sun-dial now standing to the north of Queen Mary's Tower in the royal gardens of Holyrood—a beautiful piece of work, richly decorated with the initials and appropriate emblems of the princes of the house of Stuart.

In the erection of the sun-dial he was closely associated with his two sons, John and Alexander, and in 1636 he resigned the office of king's master mason in favour of his eldest son John, and retired to Perth or Dundee, the towns where he had spent his boyhood, and where he executed various works in his old age. At the time of his decease he was master of the Ancient Lodge of Scone and Perth.

With his appointment as principal master mason to the king in the year 1636 his official career commenced. In the same year he was elected deacon of the masons and a member of the town council, and in 1637 became master mason to the city of Edinburgh, when he furnished designs for the Tron Church. This sacred edifice was completed ten years afterwards, in 1647, and was then larger than it is now. The original steeple also was destroyed by fire in the reign of King George IV. Full particulars, together with two views of the structure, will be found at pages 135-37 of the "King's Master Masons."

John Mylne was also employed by the town council to repair the great east window in St. Giles, as well as some other portions of that famous church.

About this time, as well as in 1648, the city of Edinburgh expended various sums of money on the crown steeple of St. Giles, and the upper portion of the crown may have received

* A paper by the Rev. Robert Scott Mylne, M.A., D.C.L. (Oxon.), F.S.A. (Lond.), read at a meeting of the Edinburgh Architectural Association, and published in the Transactions.

its final shape at this period, in connection with special repairs undertaken on the creation of the bishopric of Edinburgh, but the general design is evidently connected with the close of the Middle Ages, as may be proved by a careful comparison with the other ancient crown steeples of Great Britain. It is a curious fact that while we know the crown steeple of Newcastle was completed in 1474, no particular date can be discovered for St. Giles, though the meagre evidence points to somewhere about A.D. 1500.

In 1642 John Mylne executed various repairs at the abbey church of Jedburgh, and in the next year became master mason of Heriot's Hospital, in consequence of the death of William Aytoune, the successor of the celebrated William Wallace. In July 1649 the upper portion of the south-east tower was ordered to be rebuilt exactly like the north-west and north-east towers.

The times were troublous and warfare was in the air, and in 1646 Charles I. selected John Mylne as master gunner of the royal castles and captain of pioneers, while the citizens of Edinburgh sent him, in conjunction with W. Thomson, to negotiate with the officers of Cromwell's army quartered at Dalkeith early in 1652. He was also appointed to represent Edinburgh on the Commission to arrange a treaty of union between Scotland and England under the sanction of Oliver Cromwell, and the next year was present at the solemn proclamation of the Lord Protector at Perth.

As a member of the town council he took great interest in the different alterations made in the city churches under the Commonwealth, and Nicoll, in his "Diary of Transactions in Scotland," states that he and a wright named John Scott "did mislead the rest," and put the inhabitants to very heavy expenses. He also undertook the construction of additional buildings for the University of Edinburgh and repaired the Grammar School, while he represented the city for four years at the Convention of Royal Burghs. At the restoration of the House of Stuart he was confirmed in all his offices by King Charles II., and employed in reference to Holyrood. His last important work was the building of Panmure House in Forfarshire. In 1667, the year in which he died, he furnished the plans for the existing Town Hall of Linlithgow, and is simply described in the diary of Lamont of Newton as "the great master mason who departed out of this life at Edinburgh." His fine monument in the Greyfriars Churchyard is doubtless well known to every citizen of the Scottish capital.

Robert Mylne of Balfargie will always be known to fame as the builder of Holyrood Palace, which was by far the most important of his different works in the city of Edinburgh. His uncle John, whom he succeeded in 1668 as king's principal master mason, had already prepared some plans, and one of the sheets discovered in the Bodleian Library at Oxford indicates what Charles I. wished to have done had he not been prevented by untoward circumstances, as well as certain other early suggestions. The six plans drawn by Robert Mylne for Charles II. are for the first time published in the "King's Master Masons," at page 168. The last of these sheets shows the owners and claimants of the lands around Holyrood on the restoration of Charles II., and thus contains much curious information. Some of the correspondence bearing on the legal titles well illustrates the general circumstances of the times.

The curious comments of the king upon the plans actually used are worthy of note—the chimneys in the angles and corners that so offended the sensitive taste of John Evelyn, and the abrupt conversion of the Chapel Royal within the palace into a wine cellar, as well as the questions raised about the proper height for the western front and the width of the great gateway. It was perhaps fortunate that the king's ideas were not carried out in every particular. The official contract was signed at the Canongate and Edinburgh, March 11 and 12, 1672, for 57,000*l.* Scots, and particularly mentions the ornamental use of stone columns of the Doric, Ionic and Corinthian order. Due advantage was taken of foreign labour and foreign materials. Lord Lauderdale had already employed Dutch workmen at Ham, and in the detailed accounts for the building of Holyrood we find Jan Vansautvoort received 40*l.* Scots for carving chimneypieces, and the well-known De Wet was paid various sums for decorative painting. Twelve chests of French glass were supplied by David Calderwood, and white lead and marble by sea from Holland. Henry Frazer received 25*l.* Scots for furnishing English gold-leaf. The great bulk of the heavy materials were, however, provided in Scotland, and thus we find Sir W. Binning received 2,212*l.* 16*s.* Scots for twenty-nine dozen great joists delivered by him at the Palace of Holyrood, while James Bayne received 1,239*l.* 8*s.* for plaster-work. There were two further contracts entered into in the year 1676. In the first, due provision was made for taking down the work on the west quarter built by the English, or the usurpers as they are called in the previous royal warrant; and in the second, proper arrangements are made for rebuilding the fore-front wall between the two great western towers, with

a gateway of the Doric order. Here we see how the old tower of Queen Mary was the key to all the later design and the one enduring portion of the pre-Reformation structure.

By the year 1680 the palace was entirely completed, and the royal accounts of 1681 deal with expenditure on paving and the gardens, which cannot be laid out "till his majestie think fitt to order in whatt manner they are to be finished." For two centuries since that date the palace has remained without material alterations, a noble and enduring memorial of the overreign princes of the ancient house of Stuart.

Beside his work at Holyrood, Robert Mylne of Balfargie was employed on many other lesser buildings in the city of Edinburgh and various parts of Scotland. He erected the cross of Perth, taken down in 1765. On the occasion of the king's birthday in 1669, "the counsell ordaines the thesaurer to prepar tua gallonis of French wyne with tua dussone of glasses to be druckine and rune one the croce." Robert Mylne also built Wood's Hospital at Largo, consisting of fourteen rooms and a public hall. He likewise superintended the works at Leslie House, while the Earl of Rothes was attending the royal court in London. Our attention, however, must be more particularly given to the city of Edinburgh, and here in 1674 Robert Mylne was busy in connection with the water supply, and constructed a large cistern at the head of the West Bow, 15 feet by 10 feet, and 6 feet deep, as well as other cisterns in various parts of the town. The Bow Well was restored in 1861.

After erecting a bridge of a single arch over the Clyde at Romellweill Crag (now called Ram's Horn Pool) in the county of Lanark, he built for his own purposes a large stone tenement or house upon the shore of Leith, the north gable of which adjoined the Timber Bush. The ground was taken on feu from the city of Edinburgh, and the builder further undertook to construct a windmill 32 feet in diameter over the walls. The windmill is gone, but the house still stands on the shore of Leith.

Mylne's Square in the High Street and the battery in the castle also provide clear and distinct memorials of the master mason's personal activity, and connect the days of the Stuart kings with our own. Yet all such landmarks of the past are rapidly disappearing before the quick advance of modern improvements. According to the received tradition, the famous Treaty of Union between Scotland and England was hurriedly signed in one of the secluded cellars beneath the High Street frontage of Mylne's Square, the Commissioners having been driven from Moray House by the senseless fury of the mob.

Robert Mylne was also connected with the building of Writers' Court, and more specially in preparing "the great northmost room" for the occupation of the Writers to the Signet in 1696, before that honourable society had possession of their present noble and commodious buildings.

He also presented "a draught for finishing the steeple of Heriot's Hospital" in 1693, and was paid 3,100 marks for executing the same by the council. From time to time he also carried out various repairs in different parts of the historic castle of Edinburgh.

After a long and honourable public career, extending over nearly half a century, he died in his own house at Inveresk on December 10, 1710, at the age of seventy-seven, surrounded by his children and grandchildren, and was buried in the family vault in the Greyfriars Churchyard, beneath the well-known monument he had erected to his uncle's memory. His epitaph runs thus:—

Sacred to the memory of Robert Mylne of Balfargie,
Master mason to several kings of Scotland,
And surveyor to this citie,
Who during an active life of honest fame
Built among manie extensive works—
Mylne's Court, Mylne's Square, and
The Abbie of Halierud House.

Thomas Mylne of Powderhall, near Edinburgh, was the eldest grandson of Robert, the king's principal master mason. For many years he was surveyor to the city of Edinburgh, and in this capacity exercised a considerable influence on the development and general style of the public buildings in the city.

Robert, the eldest son of Thomas Mylne of Powderhall, in the year 1754 went to Italy to perfect his study of architecture, and for four years made Rome his residence, where in 1758 he obtained the Papal silver medal of the Academy of St. Luke, as a reward for his proficiency in architectural studies. "Virtutis amplissimum præmium est gloria" was the motto surrounding the delicately-chased head of Clement XIII.

On his return to Britain he was at once appointed to build Blackfriars Bridge in London, and, settling in the great Metropolis, became famous as engineer to the New River Company, surveyor to St. Paul's Cathedral, and also to the Stationers' Company. But we must confine ourselves to his work in Edinburgh, which consisted in the erection of St. Cecilia's Hall, designed after the elegant model of the Opera House at Parma, in the sunny plains of Lombardy.

Robert Mylne was also recognised as an authority on water questions, and in 1789 issued a report on Heriot's Park Reservoir, and a few years afterwards he was consulted upon the reservoir on the Pentland Hills. He died in 1811, and was buried in St. Paul's Cathedral.

His brother William built the North Bridge, so marked a feature in the central portion of the town. This handsome but ponderous structure was some time in building, and must have presented a more attractive appearance before the existing cast-iron projecting footways were affixed to the upper stonework. At the time of their addition, about twenty years ago, there was an alternative proposal to widen the bridge 20 feet by refacing the eastern side. This excellent idea (so successfully carried out at Aberdeen) was, however, abandoned on the score of expense. No funds were available for the purpose.

Though the general plan of the bridge was arranged in 1762, the foundation-stone was not laid until October 21, 1763, by the Right Hon. George Drummond, lord provost of Edinburgh, with full masonic honours. Provost Drummond had been Grand Master of the Grand Lodge of Scotland, and seventy of the brethren belonging to the Lodge of Edinburgh were present on this auspicious occasion.

For "a stone bridge across the North Loch, from the High Street, where the Cap and Feather tavern now stands, to the opposite bank at Multree's Hill," the contract price was 10,140*l*. The whole work was to be completed in 1769, and an abstract of the lengthy contract, together with the correspondence following on the serious accident to the south abutment, will be found in the "Master Masons to the Crown of Scotland," pages 253-58. We may observe three arches were to be 72 feet span each, and two of 20 feet span each. The piers were to be 13 feet 6 inches in thickness, and the total length 1,134 feet. The breadth between the parapets was fixed at 40 feet, and the entire height from the base line to the coping of the parapet 69 feet 6 inches.

This great bridge was the last important work executed by the family of Mylne in the ancient city of Edinburgh. William, the architect thereof, subsequently migrated to Dublin, where he died in 1790, being engineer to the waterworks of that city.

TESSERÆ.

The Province of *Æsthetics*.

THE mere word "*æsthetics*" is vague and poor enough; it was invented by Baumgarten to express "the doctrine of emotions," because art addresses the feelings rather than the intellect. But this, as all abstract terms, requires elucidation, and this elucidation can only be completely gained by a study of the thing, to which after a few remarks we shall address ourselves. *Æsthetics*, then, is the philosophy of art. It is not criticism, neither is it technical knowledge, but the theory of the inner life and essence of art. It is not purely empirical, like criticism, which is the knowledge of peculiar facts or laws, derived from observation of works; but the theory of art generally—the development of the fundamental idea through its particular forms and manifestations, thus deducing all secondary laws, all critical canons, from the one primary law. Such is *æsthetics* as a science—the *à priori* theory of art—the absolute statement of the conditions, means and end of art, rigorously deduced from philosophical principles. Criticism of course, if it would be philosophical, must grow out of an *æsthetical* foundation as the practical and applied form of its philosophy, and so in common conversation or writing *æsthetics* and criticism are often confounded. Nor is there much harm in this, if the empirical and philosophical natures of the two be always distinguished. When an incident, character, or sentiment is said to be not *æsthetical*, it is meant that such is a violation of the feeling which it is the end of art to produce. Prosaic passages are, therefore, non-*æsthetical*, as also are contradictions of known laws of pleasurable emotion. Criticism is to *æsthetics* what the practice of medicine is to physiology—the application to particular cases of the fundamental knowledge of the constitution and organisation of man, aided by a mass of particular observations. *Æsthetics* is the physiology of art, and as all art has a philosophical foundation, so it necessarily demands a philosophical elucidation. The necessity for a philosophical *fundus*, not only to criticism, but to all forms of speculation, cannot, one would think, for an instant be doubted, and certainly not by those imbued with German literature, where the existence of such a stratum lying underneath the whole of practical thought is the one thing prominent and distinctive.

Building Stones.

Stones, including granite, marble, porphyry, slate and the other varieties, have been from all antiquity the leading material of monumental edifices, and, except for decorative purposes, the stone of every locality has ever been employed in its constructions. We are apt to marvel at the wondrous

golden splendour exhibited in the edifices of Attica by the use of marble; but, in truth, Mount Pentelicus was in a suburb of Athens, and its marble quarries the nearest at hand. In other parts of Greece, stone, even of the coarsest grit, was used, and in the edifices on the banks of the Nile the quarries of the neighbouring hills furnished the material, as the quarries of Mocattam for the core of the Pyramids of Ghizeh. The granite of Syene and alabaster was of rare structural application, and used almost exclusively for the monolithic statues, obelisks, or sarcophagi. The general aspect of the city of Paris, where stone is the general material, and not the exceptional one as in London, has always been an object of envy to English architects. But even there the atmospheric influences act very much upon the stone, which becomes as dark as in London, a defect removed by periodical cleanings and scrapings. The small heights of the courses, especially in the frustra of the columns, as at the Madeleine, are nevertheless very disfiguring to their principal buildings. Recently, however, they are able to overcome these defects, for, by means of the railway and a greater spirit of enterprise, distant quarries of a very superior quality of stone have been opened up to their architects, and their monumental edifices have gained immensely in structural character. We in England have no reason to be dissatisfied. We have stones of the finest qualities, whether of the limestone, magnesian limestone or sandstone division. Our Bath oolite is equal to that of Paris, if only our miserable economy in some cases and the spirit of competition among unprincipled contractors, the stone merchants and quarrymen themselves, did not counteract the intention of the architect and bring into use the stone from inferior beds instead of from the soundest and best strata. There is not a better stone than our sea-girt Portland, if only properly selected, whether for its tone, its homogeneity, or resistance to the atmosphere. St. Paul's Cathedral, thanks to the precautions of the illustrious Wren, and Somerset House, may be cited to prove the enduring qualities of this material, when carefully chosen in the quarries. In these two buildings the arrises of the mouldings and angles and the very carvings still retain their sharpness. Where the south-westerly rains wash the soot and smoke from the face, the surface is brilliant and the shadows sparkling. In such an atmosphere as that of a neighbourhood where the acids of the manufacturing, as in Lambeth, are poured forth broadcast from the furnace shafts, no stone can resist their corroding effects; and it is to this, and not to the quality of the stone, that the partial surface decay of some parts of the stonework of the Palace of Westminster is mainly due.

Norman Vaulting.

The cause of the very few instances of Norman groining remaining, except in crypts, and the fair presumption that not many ever existed, is a subject open to investigation, and a speculative idea may be not without its utility in eliciting satisfactory information. Thick as the walls of that period are known to be, the risk that would have attended charging them with stone ceilings, without the auxiliary resistance of external buttresses, may have become an object of anxiety with the builders, and the execution of such works in stone may have been attended with difficulties which even at this time would be considerable, and may then have proved altogether insurmountable, except under the most favourable circumstances and amplitude of means. The centering alone, if considered for a moment, is an object involving so considerable an amount of expense and practical skill that we cannot wonder that, even in the best days of art, methods should have been devised for dispensing with it, and hence doubtless arose the adoption of wood at Lincoln, York, and elsewhere. Did not the Norman builders feel and shrink from the difficulty like their successors, but without the good fortune to hit upon so happy an expedient? We know that they affected the groin from its constant adoption in crypt and aisles, when a moderate span facilitated its execution.

Vignola's Architecture.

In treating the more ornamental style Vignola was the best among the Roman architects; but his buildings still retain something of the severity of his predecessors, and they fall far short of the grace and elegance seen in Vicenza. Within Rome he has left very little but the court of the Farnese Palace, which is not very fine, and whose style he has preposterously carried to the outside of the building to form the centre of its north-west front, although entirely discordant with the work of Sangallo. Outside of the gates are the little church of Sant Andrea and the Villa Giulia, a work of considerable beauty and great defects, and now in a very forlorn condition. The church of Sant Andrea has been much admired, and even pointed out as a model for young architects, yet it is full of faults. It is oblong on the plan, covered with an elliptical dome—a bad form, for which it does not appear that there was any sufficient reason, since a design occupying the same ground, with a square room and a portico, would have given to the front the relief that it wants, and offered a reason for the pediment which is

now placed against the plain wall. It is too high, both externally and internally, and yet with all this there certainly is united considerable beauty in the proportions and in the principal parts. In the front of the Villa Giulia the upper storey wants height and consequence, as from its distribution and style of ornament it certainly ought to be the principal. The back court and nymphaeum present in some parts a pleasing variety of lines, but there are too many breaks, and the whole is too intricate and, what is worse, whimsical. Vignola when licentious has less grace than Borromino; his forte is in correct architecture. The circular gallery above produces a very pleasing effect, and would be admirable if filled with sculpture; at present it is forlorn and naked. The most famous work of this architect is the Palace of Capraruola. It forms a pentagon with a bastion at each angle, as if it were a fortification, and may be considered to be one of those cases where difficulties were created in order that ingenuity might be displayed in overcoming them.

Masonry Construction.

The dressing of stone is a most important operation, and generally the larger the blocks the greater the care required in this particular, as to levelling the beds or dressing them in the proper angle or in the squaring. If the beds are irregular, or in winding the bearing is unequal, the stone tends to split and rend at bearing points, which act as fulcrums, and in fact may have to be loaded with an enormous weight. This cannot occur if the beds have been well levelled, as the bearing is then equal throughout the bed. The rent receives rain-water, and allows it to lodge, and the structure becomes exposed, often in a dangerous manner, to the effects of frost. If the blocks of stone are fairly and fully dressed, the trouble of laying them will be comparatively slight. Care must be taken that in order to hide or disguise a thick clumsy joint the blocks be not pitched forward on their edges, as they will then be sure to splinter at the edges, from the weight bearing on the angle. To disguise the careless dressing of blocks, and to work them when laid, workmen are apt to underpin large blocks of stone with wedges of wood or splinters of stone, thereby laying the foundation of rents and fissures when the work settles. The setting-bed of each course should be brought true and level to receive the next course, which must rest solidly and truly upon it. The face of every stone in a wall may be left quarry-faced, or as it comes from the quarry, but each stone should be wrought with a setting margin. The dressing of the beds of large blocks of stone may easily be tested, by laying the edge of a straight rod or rule (otherwise a straight-edge) along the surface of a block, from angle to angle and from side to side, when any winding or irregularities in the setting-beds will easily be seen by parts of the edge of the rule lying close to the stone, whilst cavities admit the light between the bed and the rule. In building with ashlar or other large stone care must be taken that pebble and small stones be not used in the mortar, as these will act as so many wedges on the beds; but in grouting, or filling in at the back of masonry, there is no objection to splinters being used, and in filling in angles and odd corners in rubble backing they may come in advantageously, not only to save waste of mortar, but because when the mortar sets the work will be better filled. Unfortunately, this is where masons will often not take the trouble to use splinters of stone.

Milizia's Principles of Architecture.

Architecture, like every other fine art, is subject to the following general rules:—1. In all its productions we should find an agreeable correspondence of the parts with the whole. This is known by the name of symmetry. 2. It ought to have variety, lest the spectator's attention should be wearied; and unity, which is opposed to confusion and disorder. This is comprehended in the term *eurithmia*. 3. Convenience or suitability is also a necessary quality. This consists in a just application of symmetry and *eurithmia*, and of that relation which ought to subsist between an edifice and the purpose to which it is applied; between the details of ornament and the general appearance of the building, choosing the most appropriate, and the style which accords best with the magnificence or simplicity of the structure. 4. If architecture be the daughter of necessity, every beauty which it possesses ought to connect itself with that necessity, and to appear made for some useful purpose. In every art which administers to pleasure, the artifice ought not to be discovered; everything done for mere ornament is a defect. 5. The principal ornaments of architecture are its orders, which in fact are rather to be considered as the skeleton and most essential part of the edifice than as mere ornament. We might therefore define the orders, necessary ornaments arising from the nature of the edifice. All the other decorations of architecture are subject to the same law. 6. Consequently in architecture the decoration is the result of the construction. Nothing is ever to be seen in a fabric that has not its appropriate use and is not an essential part of the structure; the office that it indicates it ought to perform. 7. Consequently nothing is admissible for which a good reason cannot be rendered. 8. These reasons are to be

deduced from the origin and analysis of that primitive natural architecture, the hut, from whence has arisen the beautiful imitative art of civil architecture. This is the pole-star of the artist in his works, and of the intelligent observer in examining them. Everything should rest upon truth and verisimilitude. What could not really exist cannot be approved, although evidently a matter of mere show. 9. Examples and authority, however they may be appealed to, will never influence him who wishes to be reasonable. These principles are constant, positive, general, because they depend on the nature of the thing itself, and on good sense. Taken together they constitute the true and essential beauty of architecture; if they are kept out of view, adieu architecture. It is no more a science or an art, but is changed into mere fashion, caprice, or delirium.

Roman Baths.

The general plan of the Roman thermæ seems to have been that of a large rectangular, central building, placed in a spacious enclosure, surrounded by smaller edifices, and on one side of this court there was a large open theatre, or rather cavea. This disposition may be traced in the three which exist the most perfectly; of the others we have not sufficient materials to decide whether it was adopted or not, and only conclude it to have been so from analogy. It is very conspicuous in the Baths of Caracalla, only the cavea, instead of being semi-circular, is in the form of half a stadium or circus. The ruins of these baths are very considerable, and are impressive by their vast square mass, and internally the immense piles of brick and rubble give it a solemnity of character with which the deep, still blue of an Italian sky is in perfect harmony, though the tints of the ruin are of rich and glowing colours. However often one may visit them, it is always with repeated pleasure that we ramble among their massive constructions. The great central chamber seems, like the great hall still remaining in the Baths of Diocletian, to have been covered with groined arches. It was probably the first instance of groined arches covering a space of any considerable extent, and as there can be no doubt that so striking a novelty would be admired and repeated, we are not surprised at finding it in all the later thermæ. It is true that Palladio introduces this disposition in his plans of all the baths, but he appears in this, as in some other instances, to have supplied the deficiencies of one by adapting to it the parts of another without sufficient authority. The great central building was composed internally of two large colonnaded courts, one at each end, and vast halls and a multitude of smaller chambers between and on each side of them; on each side of the outer circuit of buildings there seem to have been other edifices disposed circularly, and an octagonal room, which has the appearance of a hall of entrance, occurred at each end. In one of these the celebrated Toro Farnese is said to have been found. We find in the part which now remains horizontal lines, which probably mark the situations of the marble cornices, and many other indications of the enrichments which have been taken away; we trace also pipes in the wall in various places, some apparently intended to take off the smoke, while others were to introduce water.

Treatment of Flowers in Ornament.

Suppose we wanted to make a pattern of a rose for a wallpaper. We might pick one from our garden (if we had one, as, indeed, every designer ought to have) and sketch it exactly as we found it—a portrait as near as we could make it of an individual rose with all its accidental characteristics. Well, we might make an interesting study certainly, but when we came to apply it we should perceive that it made, however good as a study, a very poor pattern, and its virtue and interest as a drawing would be at once destroyed directly our pictorial rose was repeated—which we should be driven to do. We should practically get the repetition of a more or less shapeless blot, a formal and regular repetition of an informal and naturalistic drawing—a contradiction in terms, in fact. Yet it is a thing that has been attempted over and over again. A sentimental public perhaps likes roses, in season and out of season, and considers perhaps that a rose in any material would, if not smell, at least look as sweet. It may be so, but if it be not sweet and clear, in line and disposition, and organic as a pattern, its sweetness is wasted on the desert air of false art and taste and failure in decoration. Therefore it is that the designer, having regard to the conditions of ornamental effect and relation to use and material, proceeds in a very different way. He finds that a certain formalism is an essential condition of his work, seeing that his aim is to adorn a space pleasantly, to construct a pattern that will bear repetition, or rather demand it, as another essential condition of its existence. He finds, therefore, that typical and abstract forms are of more value for the purpose than accidental ones; that suggestion is better in decoration than naturalistic or pictorial imitation. He would naturally in taking a rose as his theme, recur to the primitive and fundamental type, to the simple flower as we see it on the parent stem of the wild rose of our hedges. With such a type as this he could safely make a diaper or simple-sprigged arrangement, which would be satisfactory as far as it went.

NOTES AND COMMENTS

A CIRCULAR was recently sent to the members of the Society of Architects concerning the proposed examination for membership, and inviting opinions on the project. The majority of the members agree about the desirability of such examination. The following questions were asked in the circular:—"1. Would the prestige of the Society, and of its members in your district, be appreciably raised were admission granted upon examination? 2. Were a satisfactory scheme of examination devised, would applicants, in your opinion, be subsequently attracted to the Society by having to pass it? 3. Do you think that it would be a wise step to institute an examination prior to admission to membership of the Society, due notice being given? 5. Should a register of students be opened in connection with the Society?" The replies were almost without exception in the affirmative. The fourth question was:—"Under what circumstances, if any, should admission be granted without examination, if one be instituted?" A majority of the members replied that the present system of election (which prescribes nomination by members or architects of repute, and the submission of drawings and photographs of completed works) might be applied to architects of standing and mature age. Various suggestions were also offered by the members. A report on the subject will be issued by the Council in the course of next month. The Society can of course make any arrangements that are considered advantageous, but would it not be more convincing to candidates and the public if the examination test were applied to all the members? If the prestige depends on that course, it should have been adopted at the formation of the Society a few years ago.

THE Venetians must of late years have often regretted that their labyrinthine city was not adapted as a site for an international exhibition. They have a misgiving that the "improvements" have not increased the number of visitors, who were the most profitable of all imports; and as big exhibitions are supposed to attract crowds, one might serve as a compensation for the losses which have followed the engineering works. Chicago was able to take a hint from Venice by making the exhibition buildings appear to rise out of water; but the city which "began with ATTILA and ended with BUONAPARTE" does not possess a Jackson Park of a square mile in which the nineteenth century could display its productions. As a substitute, it is proposed to hold an exhibition of works of art which is to be opened in April next. The jury will not be too exacting when judging the works that are sent. Plenty of pictures are therefore likely to be forthcoming, but whether any of them will find purchasers is less certain. The majority of artists have kindly feelings towards Venice, and there was no difficulty in obtaining patronage in all parts of Europe, as the following list will show:—Austria-Hungary—M. DE MUNKACS, L. PASSINI; Belgium—C. VAN DER STAPPEN; Denmark—P. KROYER; England—L. ALMA-TADEMA, Sir E. BURNE-JONES, Sir F. LEIGHTON, Sir J. E. MILLAIS; France—E. A. CAROLUS DURAN, P. DUBOIS, J. J. HENNER, G. MOREAU, P. PUVIS DE CHAVANNES; Germany—M. LIEBERMANN, G. SCHÖNLEBER, F. VON UHDE, A. VON WERNER; Holland—J. H. L. DE HAAS, J. ISRAELS, H. W. MESDAG, C. VAN HAANEN; Italy—G. BOLDINI (Paris), F. CARCANO, C. DALL'ACQUA (Brussels), C. MACCARI, F. P. MICETTI, G. MONTEVERDE, D. MORELLI, F. PASINI (Paris); Norway and Sweden—E. PETERSSEN, A. ZORN; Russia—L. BERNSTAMM; Spain—J. BENLIURE, J. JIMENEZ ARANDA, J. SOROLLA, J. VILLEGAS. These gentlemen do not assume any responsibility, and it has yet to be discovered whether competent persons will insure that works of art will be returned in a safe condition, and that all the efforts of custom-house officers to secure delay will be frustrated.

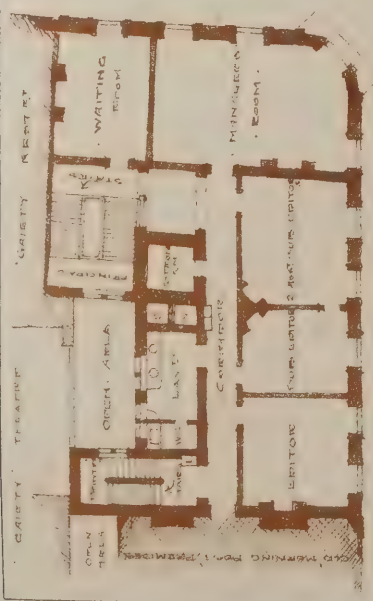

THE critical notices of the Salon, by M. PAUL LEROI, in *L'Art* are arranged this year on a novel plan. Biographies of the artists and portraits of several of them are given, as well as descriptions of the pictures. As usual, M. PAUL LEROI is trenchant in his judgments. As regards the paintings he says that the characteristic of the exhibition may be shortly expressed by the phrase "Elle est

bête." The exceptions are the works of foreign artists. The principal cause he ascribes to the efforts of the Government, who every year turn out of the schools a crowd of architects, sculptors, medallists, painters and engravers who have no aptitude for art, but are all stamped as artists and have a claim on the exhibitions. The only remedy for so deplorable a state of things was suggested to M. PAUL LEROI by one of the most eminent members of the Institut, when he said "the Ecole des Beaux-Arts must be closed immediately and transformed into a museum." Unfortunately there are political interests which are adverse to that course, and moreover, as some foreigners make use of the school, the upholders of it are able to announce that art throughout the world must suffer if any check were put on the manufactory in the Rue Bonaparte.

As political complications can arise out of trivial incidents, it is to be hoped no dangerous consequences will follow an announcement which has appeared in the *Moskowskija Wedomosti*. It stated with the gravity that becomes all political events that an understanding had been come to between the Emperor of GERMANY and the Shah of PERSIA respecting the paintings belonging to the Eastern monarch which are in Munich. It is easy to imagine how amazed were the diplomatists at the intelligence, for it would appear as if the Shah had contrived to evade observation, and from time to time found a refuge in the Bavarian capital. Some hours elapsed before the truth became plain. Then it was found that the startling piece of news was created by a newspaper correspondent whose vision was too keen. Among the collections of pictures in Munich is one which belonged to Count SCHACK. On his death, which occurred lately, he bequeathed it to the German Emperor. The people of Munich were disappointed, and there was some commotion when it was stated that the pictures were to be removed to Berlin. The Emperor took a right view of the case, and decided that they were to remain in Munich. The Moscow paper, and probably several others, obtained a version which may have lost nothing on its way, and Count SCHACK'S pictures were converted into those of the Shah.

IN these days, when the cheapest literature has a hard struggle for existence, since free libraries and other philanthropic institutions supply all classes of books without any payment, it is refreshing to learn that the Baron von GEYMÜLLER proposes to bring out a "Thesaurus of Architecture" which is to cost 1,000*l.* a copy. It is a project worthy of an art which has so little modernity. The American architects, to whom a communication has been addressed by the Baron, have not sufficient appreciation of antique modes of building or trading to accept his proposal unless there is some modification of the conditions. They consider that the Baron ought to agree to print a larger number of copies, in which case the "Thesaurus" could be sold for 200*l.* But the projector would have more chance of finding thirty people who would be willing to pay 1,000*l.* for a fad than one hundred and fifty who would care to pay the smaller sum. The chief interest of the book will be its costliness and rarity, for we doubt if ownership of the "Thesaurus" would afford much aid to a competitor, or would enable a layman to become his own architect and be secure from the litigation which commonly follows such an experiment.

THE purchase of modern French paintings in England has become so common that a transaction of the kind rarely attracts attention. There is not much reciprocity in France, especially in dealing with pictures, and an English artist who finds he has attracted a buyer by exhibiting a work in the Salon has some reason to suppose he is possessed of unusual merit. Mr. J. H. LORIMER is in that favoured position. His *Benedicite: fête de grand'mère*, showing a family around a table, which is lighted by candles having yellow shades, has been secured by the French Government. Mr. LORIMER has studied in Paris under M. CAROLUS DURAN, and he has already received a medal from the Salon. In the Royal Academy Mr. LORIMER has one work, *The Eleventh Hour: Mariage de convenance*, which is of the class that has attractions for the crowd.

346 STRAND, W.C.—EXTENSION OF PREMISES FOR THE "MORNING POST."

OUR illustration shows the new extension of premises of the *Morning Post*, which has been recently completed at the corner of Wellington Street and the Strand, and adjoining the old premises in Wellington Street.

Externally the general lines of the old building had to be followed, the materials used being red brick and Portland stone. Internally the accommodation provided includes advertisement office and cashier's department on the ground floor; manager's department and additional rooms for the editorial staff on the first and second floors, caretaker's rooms on the third floor, and an extension of the composing-room and reading-rooms on the fourth floor. In the basement is the machine-room, including new boiler and engine, with coal stores, &c., and set of new web printing machines by FOSTER, of Preston.

The building is of fireproof construction throughout, the floors being on FAWCETT'S system and the internal partitions of concrete and iron, wood being only used for joinery-work and fittings.

The general contractor for the work was Mr. D. CHARTERIS, of Westminster, the hot-water work being carried out by Messrs. ASHWELL & NESBIT, and the electric lighting by Messrs. BERRY, HARRISON & CO. The architect was Mr. H. O. CRESSWELL, of 30 Craven Street, Strand.

WHITE HART HOTEL, BLACKWATER.

THIS hotel has been rebuilt for Messrs. MAY & Co., Basingstoke, and stands on part of the site of the old building, which has been pulled down owing to its unsafe condition. The new building is much larger than the old one. On the first floor there is a large assembly-room used for balls, masonic and other purposes.

The facing bricks are of a deep red tint, supplied by LAWRENCE, of Bracknell, and the tiles of a dark red colour, by BREWERTON, of Caversham. The work has been carried out by Mr. J. HARRIS, contractor, of Basingstoke, from the designs of Mr. GEORGE W. WEBB, Market Place Chambers, Reading.

LONDON AND ITS ASSOCIATIONS.

A PARTY of Americans have arrived in London as sharers in "An Old Country Pilgrimage," organised by Bishop Vincent, of Chatanqua. On Thursday last Mr. Walter Besant read a paper entitled "London and its Historical Associations" for their benefit in the Westminster Town Hall.

Mr. Besant said London now meant an immense city, scattered over a hundred square miles, with five millions of people. Three hundred years ago London meant nothing but the ancient City and the Borough. Two thousand years ago, or thereabouts, the City of London was first begun. At that time the Thames valley was a vast morass, sometimes flooded at high tide. Thames Street, the heart of the City, was the first part built and settled—the first cradle of the great trade of England—and it continued to be the chief centre of trade. The people whom the Romans found here, the trade which had already made the town important, might have been settled, might have been growing, for all we know, during hundreds of years before the Romans came. The City marked out so long ago by the Roman wall never got beyond the wall. To this day the Lord Mayor was the chief magistrate of the area, a mile long and half a mile broad, marked out by the City wall. It was not till the seventeenth century that London was fairly filled up to the walls, and was running over on the north, east and west. Small as was the area of the City, it formerly contained 114 parish churches. Some of these were not rebuilt after the Fire, and a few yet survived which were not burned down. St. Paul's Churchyard was formerly enclosed by a wall and provided with four gates. The wall followed what was now the line of houses. In the north-east angle was a slab of stone with the words "Paul's Cross" carved upon it. On this place met the old Folkmote, the parliament of the people. Three times every year the citizens were called together by sound of the big bell of the cathedral, to hear and to discuss at Paul's Cross, freely and openly, all men being equal, things belonging to the welfare of their city and their trades. That Folkmote

was the foundation of all our freedom. There was a great deal more of history belonging to Paul's Cross. This was, to his mind, the most sacred spot in the world. It stood for the government by the people; for freedom of speech and for freedom of thought; for all the rights that we had made our own; for the abolition of religious authority. In an old-fashioned way he still continued to think that we were what we were, on either side of the Atlantic, because we had what Paul's Cross gave us. There was one civic institution in London which had never passed over to America. He meant that of the City companies. The reason was that when New York and Boston rose to importance the trade companies of European cities had practically accomplished the work for which they were founded. But they ought not to leave London without some consideration of the City companies. They sprang out of the guilds, and the guilds were at first religious associations. Every trade had its patron saint. The men being thoroughly educated in the duty of organisation, every trade guild became a trade company, with a royal charter, a coat-of-arms, a master and wardens, a livery, and a complete set of rules, to which the members owed obedience. When the suburbs grew up, when the working man left the boundaries of London, the power of the companies decayed. Their estates remained; a few of them were rich; they now used their revenues for the advancement of many noble enterprises, charitable, educational, technical. Down to the reign of Charles I., outside and inside the City wall there were heaps of ruins, those of the religious houses. It took many years to remove the ruins of these monasteries. Fragments remained to this century; indeed, they might still stand in the church of the Augustin Friars, and see all that was left of the Franciscan cloister. In Milton's time the sites were yet cumbered with the ruins. None of the English poets or dramatists seemed to have perceived the pathetic and the poetic side of the ruins. The ancient faith, although stubbornly retained by a few Englishmen, was never regretted or lamented by the greater number. In a single generation it was clean forgotten. If they would connect London with kings and nobles, there was, first of all, the Tower, the citadel or stronghold of London. It was built not so much for the defence as for the domination of the City. The Tower was placed beside the river at the extreme east. For two hundred years and more the citizens never looked at the White Tower without suspicion and hatred in their hearts. Then came a time when the Tower ceased to give them any uneasiness. It was when they knew and felt their own strength. They could supply the king with money and with soldiers. More than that, they could move as one man; if they chose they could dethrone the king. It was London which deposed Edward II.; it was London which finally defeated Charles I.; it was London which caused James II. to fly, and lastly, it was London which brought over George I. from Hanover. The Tower had long ceased to be a palace or a fortress; it became instead the principal prison of State, the Mint, the Armoury, the Record Office, and the treasury of the Crown jewels. But it was first and foremost a citadel to command the City, and it only ceased to be so when the king discovered the grand advantages of keeping the City in good temper. There was another view of the Tower. If Westminster Abbey contained the tombs of the great men who had succeeded, then the Tower contained the bodies of those who had failed—if imprisonment and death meant failure. Here was the poor innocent child of sixteen (Lady Jane Grey), here were Catharine Howard, Anne Boleyn, Sir Thomas More, the Duke of Monmouth, Sir Walter Raleigh, and so many others who had suffered death upon the scaffold. Westminster Abbey illustrated one side of English history, the chapel of St. Peter ad Vincula the other side. There were other royal residences in London, but one could only show them the sites, and in some cases the names, which survived. If they should see the words "Tower Royal" at the corner of a narrow little street they might be interested in it if they remembered that Queen Philippa had her wardrobe there; if they read of Bridewell as a place of correction, it was formerly a royal palace; if they should happen to look into a little secluded square called Wardrobe Place, it was the site of one of the courts of the palace called the King's Wardrobe—the church close by was St. Andrew's-by-the-Wardrobe. When they walked down the Strand, they passed the precincts of the Savoy. It was the palace in which King John of France, our prisoner, died. It was also the palace of John of Gaunt. And when they read of a ward called Castle Baynard, remember that Baynard Castle was a royal palace in Blackfriars. In the fourteenth century the nobles' houses were mostly within the walls. A noble had to find accommodation in his house for all his followers. The Earl of Warwick went about with a following of 700; Cardinal Wolsey, later, had a following of 800. These houses, in fact, consisted of open quadrangles with buildings round them. If they went to Hampton Court they had in the first two courts a town house very much like one that might belong to the Earl of Oxford in the fourteenth century. There were between thirty and forty of these great

houses in the City at the least. There were, next, the offices of the City companies, about eighty in number, most of them with their halls. And, next, they must consider the houses of the rich merchants. If they wanted to see what kind of lodging was thought suitable for a rich merchant of the fifteenth century they should go to Crosby Hall, of which a large portion still stood. In its splendid hall, now a restaurant, sat Richard of Gloucester, waiting to hear of the death of the two boys who stood between him and the Crown. Add to these great houses the splendid monastic buildings of which they had already seen the ruins, and he thought they would acknowledge that London was really a city of palaces. As to the literary associations of London, they formed a branch of inquiry quite beyond the reach of a visitor unless he stayed a long time in the City. He would illustrate this difficulty by a note on Milton and his places of residence. Milton was born in Bread Street, at the sign of the Spread Eagle, under which his father carried on the business of scrivener—that was a writer of agreements, leases, contracts and partnerships, and perhaps a moneylender as well. Where was the sign of the Spread Eagle? We did not know. There was Bread Street, but the house with the sign of the Spread Eagle was burned in the Fire. He was baptized in the church of All Hallows, at the corner of Bread Street; the church was gone. He was educated at St. Paul's School; the school was removed to another part of London. He lodged in the house of one Russell in St. Bride's Churchyard; the house was said to have stood at the back of the office of *Punch*. He removed to Aldersgate Street; the house was gone. Thence he went to the Barbican; the house—No. 17—was not pulled down till 1864. His next house was in Holborn, the house looking out into Lincoln's Inn Fields. Where was that house? No one knew. Then he had a house in Westminster; this house was only taken down in 1877. After the Restoration he went into hiding in Bartholomew Close, in which house was unknown. He then lived in Red Lion Square, Jewin Street, and Artillery Walk, Bunhill Fields. It was only two hundred years since Milton died; most of his places of residence were without the area of the Great Fire, and yet not one of the houses in which he lived now remained, nor could even the site of most of them be distinguished. This illustration would be a sufficient reason for any omission of the literary associations of London. In conclusion he bade them welcome to London. He hoped that their visit, too brief, might yet prove an introduction to the study of the civic history which was the precursor of their own civic history, from whatever American city they came. It was a city which all Americans loved to explore. It had been the creator and the champion of their own liberties. Among their ancestors—since all Englishmen of days ago were their ancestors—Chaucer, Lydgate, Ben Jonson, John Milton, Dryden, Addison, Pope, Goldsmith, Dr. Johnson, without counting later writers, loved London. Milton, above all, loved his birthplace with all the strength of his deeply passionate heart. "Behold," he said, "this vast city, a city of refuge, the masonic house of liberty, encompassed and surrounded with God's protection. The shop of war hath not more anvils and hammers working to fashion out the plates and instruments of armed justice in defence of beleaguered truth than there be pens and heads sitting by studious lamps, musing, searching, revolving new motions and ideas." It was speaking of his own time and of the Republican ideas which possessed the more generous and the nobler spirits of the age. Or, to quote Cowper's translation of Milton's Latin, he wrote of London:—

Oh! city, founded by Dardanian hands,
Whose towering front the circling realm commands.
Too blest abode! No loveliness we see
In all the earth, but it abounds in thee.

THE WEST FRONTS OF FRENCH CHURCHES.

THERE is a certain similarity in the disposition of the western front in all the French churches of the thirteenth century. The cathedrals of Amiens, of Notre Dame at Paris and at Rheims, are distinguished from our English buildings by nearly the same particulars, though they differ much from each other. They assume in this part more of a pyramidal form; the space between the western towers is proportionally smaller than with us. The doorways are much larger; a rose or marigold window is placed over the central opening, and above that is one or more ranges of niches, with statues nearly hiding the triangular gable end of the nave. Sometimes one or even two ranges of niches occur below the marigold window. Occasionally the window is between two ranges of niches, and in some instances there are two rose windows. These windows and niches form the elements of the composition, but the arrangement varies in almost every edifice.

LETTER IV.

HAVING in my last paper endeavoured to trace the succession of changes which took place in English architecture from the time of the Romans till a period in which Italian architecture became common, I propose in my present communication to treat of the architecture of a part of France in the same way. It seems likely that the Romans left some better works in France than in England, for there is still remaining that beautiful specimen of Corinthian called the Maison Carré at Nîmes.

At Lillebonne a Roman theatre has been within a few years discovered and laid open.

At Bayeux the pulling-down some old houses has laid open for a short time (for other houses are building) a portion of the Roman wall of the city, within a few feet of which a fine gold medal of Valentinian was found.

At Rouen is the church of St. Gervais, which is clearly made out by the French antiquaries to be about, if not before, A.D. 350 for the crypt, and the upper part of the east end to be before A.D. 1000.

At Beauvais is the remain called the Basse Œuvre, or Low Work, as compared with the very lofty work of the new choir. This is considered the remains of the ancient cathedral, and it stands where the nave of the present cathedral should stand. This building also the French antiquaries consider of a date before A.D. 1000.

All this succession of building is of the same character; all have tiers of Roman bricks or tiles running as bonds horizontally and round the arches in nearly all the examples. All have their arches plain semicircles, and all are built with small stones and very large joints. At the Basse Œuvre at Beauvais, the lower arches remain; they are perfectly plain, and have plain square piers. At St. Gervais, Rouen, the crypt has a plain impost at the spring of the arch, much like that which continues with a plain arch almost as long as the semicircular arch itself remained. The upper part of the east end of this church, over the crypt, has regular columns just engaged, perhaps 3 inches in a diameter of near 2 feet; they are about 10 diameters high, have regular bases and capitals alternating Corinthian and Ionic; both capitals and bases are much mutilated, but can be made out; there is now no entablature.

About the year 1000 there appears to have begun that style which may, I think, justly be called Norman; for under William the Conqueror and William Rufus, we have both in France and England a series of magnificent works in a style so much the same that to an ordinary observer they would appear identical.

The two buildings which have much engaged the attention of the French antiquaries from their different character—the abbey of Jumièges and St. George de Bocherville—appear to have been finished about, or soon after, 1050. They are clearly fully-formed Norman; but one of them, Jumièges, is remarkably plain and the other much ornamented.

On an attentive and careful examination of these edifices, I do not think there is any difficulty in considering them of the same date. Some of their mouldings are nearly, if not quite, the same, and the composition in both bold and simple.

Shortly after these we have the magnificent churches at Caen—St. Nicholas, now cavalry stables; Trinity Church, or the Abbaye aux Dames, now the chapel of the hospital; and St. Stephen's Church, or the Abbaye aux Hommes.

There are also many small churches in which Norman portions remain.

It should be remembered that in speaking of these buildings it is only the Norman part which is spoken of, for almost all these churches have only a part Norman. At St. George de Bocherville nearly the whole of the church is Norman, but the chapter-house and other adjuncts are much later. At Jumièges only the nave and a few other small parts are Norman; the choir of the Abbaye aux Hommes is much later.

The character of the capitals is very various in these edifices, but hardly any of them are very materially different from those in England, except that a greater resemblance to regular Corinthian capitals is found, and at times an approach to Ionic. Very large and deep doors are not very common, but at St. George de Bocherville is a fine one.

Straight-headed apertures under semicircular arches are about as common as in England; and the zigzag, billet, fret

and other enrichments, are much the same. Windows are some plain, some ornamented; many one lights, but some two lights, with the usual pillar centre, and the two round heads under one semicircular arch.

It is just as difficult to ascertain the exact date of the introduction of the pointed arch in France as in England; but when once it was introduced it was mixed with the semicircular one in a more capricious way than in England; for here there is a little consistency in its use when mixed with other shapes, but in France its use seems to have been governed by no assignable rule, and frequently a pointed arch occurs at the very bottom of a building and everything above is Norman. From these circumstances I cannot but think that the use of the round arch, with Norman details, was continued there quite as late, if not later than in England.

A claim has been set up by M. de Gerville for a very early date for the cathedral of Coutances; but, having visited and carefully examined this cathedral, I cannot consider it entitled to an earlier date than about 1220 or 1230; and I think that any one acquainted with the architecture of England and France will consider it useless for M. de Gerville to continue a claim which would, if proved, throw all reasoning from the character of buildings into inextricable confusion.

the waving of a flame, and the tracery of the windows of this style (which are the great but not the only distinguishing feature) gives very forcibly the idea of this waving in its dividing lines.

I have been compelled in some degree to anticipate in the foregoing paragraph in order to give at once the names I propose using, and here may perhaps be the best place to introduce the general corrective remark alluded to above.

In England there are few whole edifices of one style only, and even where there has been a building carried on upon one plan to completion, we sometimes find that, though the plan is retained, either the forms or the mouldings of the portions executed at the later periods are more or less adapted to the style then prevalent. Of this Westminster Abbey and the cloisters at Norwich afford examples. A second source of difficulty in assigning buildings to their proper styles is that a form common in an earlier style is continued for a long period in some particular buildings after it has been almost or quite extinct in other buildings; this is rare in England, but some examples are to be found.

In France both these sources of confusion occur to a great extent, and some buildings which have been very long in erecting have both. These anomalies in some districts are

A FRENCH FLAMBOYANT WINDOW.
St. Germain at Pont Audemer.

The French antiquaries, and principally M. de Caumont, in his essay in the "Transactions of the Antiquarian Society of Normandy," have divided their styles in a way different from my own division; but as a very careful examination of the French monuments does not bear out that clear distinction of the different dates which would be required for the adoption in England of all his divisions and their names, and, as the principal points are coincident in both countries (with the general correction I shall shortly state), I think it best to retain, as in England, the word "early," calling that style which began about 1200, and lasted till about 1300, Early French, to which those who wish to add Gothic may add the term if it is any benefit.

The next period, from 1300 to 1400, I call Decorated, as in England; but the last period, after 1400, being in its arrangements so peculiar and so different from our Perpendicular style as to require a different and particular appellation, I take the name given it by M. de Caumont, which is peculiarly applicable, and very easily understood by any one who will spend a short time at Rouen only in examining the buildings of this style. M. de Caumont's name is Flamboyant, alluding to

more prevalent than in others, and an illustration in point may be taken from the steeples about Caen and in other parts.

Those of Norman date had in some of the stages several compartments of panelling, of which the alternate ones, or if four the two middle ones, were pierced for windows; these were often, if the steeple was lofty, of a long proportion; when the next style came of course, according to the usual character of that style, they were lengthened, and when the Decorated style was formed these long windows continued to occur, but they were a little modified by being made very small two-lights, yet the same general appearance of these steeples was preserved by this adaptation for nearly 400 years, and so nearly is the outward form alike that it requires a close approach to discern what the real style is.

One other instance of resemblance in the details of very different periods may be found in the spires being cut in tiles or shingles; this begins very early and continues very late. This illustration will, I trust, explain my meaning, and I may also remark that in France there is much more mixture of the features of different styles in the portions of buildings that were erected at the same period than we generally find in England.

Although it is evident that the gradation in France, from the Norman style to the Early French, was carried on as in England by imperceptible degrees, yet we are not able to trace it so clearly from the continued tendency to Norman mixtures, which lasted till the style again changed to Decorated.

We have therefore in each church a greater or less mixture and very few pure buildings like our Early English in its confirmed state, and before the enlargement of windows, which marks our later buildings of that style and forms the transition to the next. Of these pure buildings we found two so very excellent that they deserve especial mention. One is the church of Norrey, near Caen, a cross church, with a lofty steeple and a circular apsis, with chapels. The other, the chapel of the Seminary at Bayeux, which was a monastery, and the buildings are mostly modern, except the chapel, which has lately been cleaned, and some restorations executed not in the best style; its beautiful porch is, however, still in a ruinous state. This chapel is a single plain-groined space, with double lancet windows. It is in character and simple beauty more like the eastern portion of the Temple Church than anything we saw. This chapel has a curious eastern termination, which will be noticed when that subject is treated of.

A FRENCH FLAMBOYANT WINDOW.
Over the Doors in the South Porch, Harfleur.

Norrey has its choir and north porch of a much richer character than the Seminary chapel, but still in its details, mouldings and foliage very pure and much like English work.

These examples, with various small portions occurring in different buildings, are sufficient to show that, although not always (perhaps I might say not often) so worked, yet that the Early French style when pure was very much like the Early English. During this transition and that to the next style many very large buildings were begun, and the Early English base of piers (the attic base worked to hold water) is as common in France as in England, if not indeed more so. During this time also the piers have varied, though not exactly as in England, yet so much so as not to require particular enumera-

tion, except in one case arising from the general plan of finishing the eastern portion of the French churches: this in very nearly every large church and a great many small ones is with a circular or multangular apse, and this rendered it convenient to use a pier very seldom. If ever used in England that is a double column engaged in each other, the plan forming a figure of 8, one shaft to the choir and the other to the aisle. This arrangement is continued from very Early French to very late work, and at one cathedral these shafts have been fluted in modern times.

As the cathedral of Amiens is usually contrasted with Salisbury Cathedral, it will be proper here to notice the portal, or grand entrance, which forms so important a portion of most of the western façades, and in many of the transept ends, of the larger French churches. They have in most instances the centre doors double, and in far the greater number the head of the actual doorway is a straight line leaving a large tympanum. The sides are often very deep, far beyond almost any English Norman doors, and are very generally filled with saints of very large dimensions in niches which are continued up the sides of the arches, and thus with the tympanum, which is also often carved with statues in niches or relieved figures in groups, forming a mass of statuary which at a little distance becomes confused, and the straight line at the head of the door having above it other straight lines of figures, the whole has a very unsatisfactory appearance from the arches being abruptly cut by these straight lines. This mode of ornamenting the portals began about 1200, and continued more or less to the latest period, but not to quite so great an extent in the Flamboyant style, as some of the transept doors of that style are not so overpowered with statuary.

It may be well to remark that the nail-head and toothed ornaments, though found in France, are by no means so abundant as in England; there is, however, a great similarity in the style of carving at the same date in both countries.

The enlarged windows, which led on in both countries to the Decorated style, appeared apparently at an early period, as parts of Amiens have real Decorated windows, but it is not absolutely clear that they are so early as the walls, for many practical reasons might occur to defer the windows—the tracery at least—till a later period. However this may be, there seems to have been a rather abrupt assumption of windows with geometrical tracery, much of which, from the large size of the churches, is very beautiful, and very soon appeared the glory of the French large churches—their magnificent wheels. In this particular we cannot compete with France. I am not certain that we have twenty wheel windows in England which for size and tracery can well be named, while in most of the cathedrals in France there are one, often two, and sometimes three, and they are of all dates, from Early French to the latest Flamboyant, and from their size are often very elaborate, and many of their large windows have wheels of very rich character in their heads. The advance of flowing tracery not Flamboyant does not seem to have taken place in France so completely as in England, the tracery continuing apparently longer of a geometrical character, and then almost at once becoming Flamboyant.

As there appear to be few pure Early French buildings, there appear to be as few pure Decorated ones—that is, buildings the style of which is without a tendency either backwards or forwards—but there are many portions, and one chancel of a small church, Tour en Bessin, near Bayeux, is so beautiful, and so completely harmonises with our best English Decorated work, that it deserves especial notice. It is a cross church, the nave Norman, and the aisles destroyed and the arches built up, a central tower and transept. The tower and spire seem earlier than the chancel, which has very large windows above a lofty arcade. In this arcade (now very much mutilated and part converted into cupboards and shut up) there have been two rich piscinas and three stalls. There may have been more stalls, but they are not now visible. Above this arcade a band of quatrefoils ran under a cornice and pierced parapet, with a passage between it and the windows. The chapel is beautifully groined, and has had a south door, the outside of which remains. All this work is of the purest character, and the mouldings bear a great analogy in character and combination to some of our best English Decorated work.

This church renders it necessary again to revert to the finishing of the east ends of large and small churches. After 1200 it appears during the prevalence of the Early French style to have been not uncommon in smaller churches to have the east ends flat, for we found many country churches with three lancets and a flat east end, but of these nearly all were stopped. A few east ends we also saw with Decorated windows at the east end, and the end flat. One large church in a town (Louviers) between Rouen and Evreux, the date of which is known to be 1218, had originally a flat east end and lancet, but now has a plaster addition to make a sort of circular apsis.

As a curious sort of intermediate finish of the east end, the chapel of the Seminary at Bayeux and this Decorated chancel

at Tour may be cited, and I know not that we have anything like either of them in England. The first is easily described. At the east end one shaft rises in the middle and another behind it, then on each side of this shaft a recess, being three sides of an octagon, is formed, thus giving a singular and very beautiful finish, and still more beautiful groining, to the east end. I suspect this east end had originally two altars.

At Tours another and much more elaborate composition is exhibited. Here we have the east end divided into three arches, the middle one containing a very fine five-light Decorated window, and each side arch having three sides of an octagon outwards, two of them with two-light windows and the other with a one-light window, all with good and varied Decorated tracery. The arcade, which is inside the side windows, also runs inside of these polygonal portions, and is separately groined from its own shafts, and then the principal space again groined; the intricacy and beauty of this roof altogether I have seldom seen exceeded. It is not easy to describe this in words, but I trust a plan of the groining will make it clear. The choir of St. Ouen at Rouen, and some parts of the transepts of this church and the cathedral, exhibit fine specimens of the French Decorated style.

It may be proper here to remark that the cathedrals of some of the southern parts of France have various portions and combinations strikingly recalling their vicinity to Italy and the modifications thence arising; but this subject belongs to that

Early English work, and is continued and used indifferently with the trefoil to the latest time. In France, though it cannot be said the cinquefoil is never used, yet the trefoil is so constant that cinquefoiled examples are very rare.

In many of the large churches, such as the cathedrals of Amiens and Rouen, and the church of St. Ouen at Rouen, and at a few other places, the triforium is glazed as a window, and being in these instances large and lofty and filled with stained-glass, has a very fine effect.

Of the stained-glass I may say that it is astonishing that so much has been saved as is still remaining, and its quality is mostly very good indeed. A careful examination with a good telescope is (from its distance from the eye) essential to a proper appreciation of its value.

I have said little of the minor adjuncts—screen-work, wood-work, &c.; but I may here mention that the cathedral of Evreux alone contains a complete mine of beautiful enrichments and tracery in wood screen-work, and in iron locks, handles, &c. The beautiful shrine of St. Taurin in that city is a complete silver-gilt cross chapel, of the best Early French character and most admirable execution and considerable size, being about 5 feet long, 2 feet wide, and 3 feet high, having many fine figures appearing in the arches, and beautiful foliage in the crockets, &c.; if executed in stone as a chapel it would make a very fine building. Other edifices contain portions of screen-work, &c., of great value, and I believe some at

more minute view of each style which I propose to take hereafter.

Before proceeding to the last or Flamboyant style, it is right to notice the continuance nearly through all the styles of that most simple mode of groining which, with us, is characteristic of the Early English style; and I think this is easily accounted for by the greater height, not only actual, but proportional, in the French edifices, which rendered useless the elaborate groining of our lower proportioned churches, for the carving of the bosses, with us so beautiful, would be utterly lost at the distance and the angle it would be seen at in French churches. That the French architects did it from choice is evident from the occasional use in proper places—small chapels, niches, &c.—of very elaborate and beautiful groining, but I do not recollect seeing any real fan tracery, though some roofs have pendants.

It may be well here to notice two singularities which run through all the later French styles: one is the absence of all battlements, properly so-called, whether real as parapets, or ornamental in buttresses, niches, &c., where they are so frequently used in England; instead of them we have a profusion of pierced parapets of elaborate composition. The other ornamental difference is in the feathering or cuspidation of arches in tracery, &c. In England, although the earliest feathering is generally a trefoil, yet the cinquefoil is used in

least of the silver utensils, crosses, lamps, &c., are of ancient date.

I now proceed to the last, or Flamboyant style. Like our Perpendicular style, it seems to have come out nearly at once, as we see very little transition from Decorated to it, though the nave of St. Ouen is such in some degree, but perhaps in a greater degree an adaptation of the latter style to the character of the choir.

Like the Perpendicular style, its piers are often without capitals, the mouldings running into the arches; like the Perpendicular, it has a variety of bases to its piers and also a variety of small buttresses to its niches, and it has also that interpenetration of mouldings and piers with bases, taking one set of mouldings and missing another, which is so common in the English Perpendicular. It has its mouldings flattened and with large hollows, like English later work; but with these points the agreement nearly ends, and the styles are in other points curiously contrasted. Although the Perpendicular style admits of great richness, we find it often worked very plain, yet retaining all the real character of the style, while plain Flamboyant seems very uncommon in France.

Its essence seems to be elaborate and minute ornament, and this continues till the forms and combinations are sadly debased and a strange mixture of Italianisms jumbled with it. Its combinations in the earlier part of the style for richness,

elaborate ornament and magnificent design are admirable, and no one can visit Rouen, where there are many churches still used and others now desecrated, and contemplate leisurely the beautiful church of St. Maclou, without feeling the value of the style, and also the value of that fine stone which seems to have encouraged the Flamboyant architects to vie with each other in elaborate decoration. The portals of Abbeville, Beauvais, St. Riquier, Evreux and of St. Maclou at Rouen, parts of Caudebec church and various other churches, are some of the finest specimens of this style.

Some of the towers of this style are very fine, but too often mutilated, and the spire of one of the western towers of the cathedral of Chartres may also be mentioned as a fine specimen. I might add Harfleur and some other smaller churches.

The combination of tracery called Flamboyant is not easy to express in words, and we have very little like it in England. An example or two exhibited will be the best explanation.

As in England, during this style a material alteration took place in the arches of doors, windows, &c., and in the same direction, viz. to become flatter; but it is curious that it took an entirely different direction. While the English four-centred arch kept getting flatter and flatter, till it became a mere turn for the small arch and a straight line for the larger one, it still preserved a point, and, even when flattened so as to rise only a few inches, still preserved its character. Of this arch I can find no distinct trace in France, though I will not say it does not exist, but its French companion, the flattened arch of the Flamboyant style, which is used as much as our four-centred arch, is a very simple one, consisting of an absolute straight line in the centre and the angles rounded off with a quarter circle, giving more or less height to the arch as the radius of the quarter circle is greater or smaller. In domestic work the aperture often becomes a straight line with a drip or other ornamental moulding or canopy over it. This style is exhibited in wooden domestic work in many parts of France, gradually adopting more and more Italianisms till they overpower all traces of Gothic.

In churches it is not so easy to trace the debasement, but parts of some churches at Caen show it clearly.

Of the details of this style I have little more to say; but I must notice two very disagreeable piers which are not uncommon in this style. One is a series of eight hollows and eight rounds without fillets; this pier has a capital to each round, but it looks very poor and meagre from the want of fillets. It is used at Beauvais and some other places. The other is a plain round pier with no capital, but the mouldings jumping out of the pier side, as if they had been soft and the pier stuck up into them. I know not that we have anything like these in England.

I have heretofore noticed the very capricious omission and insertion of the drip moulding in all the French styles, and both inside and out. In England the nature of the material, or some other apparent reason, occurs for this omission; but in France, I can discover no law or local reason for its use in some instances and its omission in others. I may also notice that the flat character of the primitive Norman arch faces, with perhaps a large bead for the only moulding, continues to appear to a late date, and in some degree to operate till the two hollows of the Flamboyant style supersede that flatness.

From the very great height of the large churches this character will be little noticed; but a good telescope (which is especially required to see many things in the French churches) will soon discover the absence of those rich suits of mouldings so common in the arches of our large churches.

As one more characteristic of the Flamboyant style may be noticed the use of a small number of very large crockets in the canopies of large portals; the effect produced is very fine, but very different from any of our Perpendicular combinations.

There are many more remarks I have to make on the minutiae of the progress of architecture within my assigned limits, both in England and France, but I must reserve them for that comparison, style by style, which I propose, if favoured with health, to make more at large; but I hope I have said enough to induce those who have time and opportunity to study the styles of architecture in different countries, not as contradictions, but as members of the same family with local differences.

If this is done with a basis of extensive English knowledge (for I still think that in England will be found the most clearly marked features of each style in its purity) then will every succeeding essay, giving details of buildings in any part of Europe, be eminently useful, and lead the way to what is much wanted, a general statement of the progress of architecture in Europe; and why may this not hereafter enable us to acquire some systematic knowledge as to the Mohammedan and Hindoo buildings, to which we are but strangers at present?

It will give me great pleasure if any member of the Society who has visited other parts of France, which I have not, would give some account of what he has found there.

(To be continued.)

DUNDEE INSTITUTE OF ARCHITECTURE.

THE Dundee Institute of Architecture, Science and Art held a meeting in the hall of the Young Men's Christian Association. Mr. William Mackison, F.R.I.B.A., burgh engineer, &c., president of the Institute, in the chair. The competitive works submitted by various students were exhibited and examined, and the Council's decision thereon was confirmed. Mr. Archibald Campbell, Albert Street, Dundee, received an honorarium for his sketch of a fountain and of the interior of St. Paul's Episcopal Church. He was the only competitor in Classes 3 and 4. Mr. Thomas Ross, jun., St. Peter Street, was awarded a prize for his sketch in water-colour of *Gladiator*, and Mr. William S. Dick an honorarium for his sketch in black and white of *Venus of Milo*. Both sketches were from subjects in the Dundee Art Museum of Casts. In Class 8, for architectural or geometrical drawing by artisans, an honorarium was awarded to each of the three competitors, their work being all alike good. In Class 9, for design for lodge and gateway, Mr. D. W. Galloway, Ramsay Place, Broughty Ferry, secured the prize, and Mr. John R. Barbour, The Beeches, Blairgowrie, an honorarium for merit. The President was thanked for his addition of 10s. 6d. to the prize fund. The following gentlemen were nominated as office-bearers for the ensuing session, viz.:—President, ex-Bailie Keith; vice-president, Mr. Leslie Ower; members of Council, Bailie Foggie, Messrs. G. G. Maclaren, William Briggs and William Nixon; honorary secretaries, Messrs. J. J. Henderson and G. Jamieson; honorary treasurer, Mr. R. Hunter, and auditors, Messrs. Thomas Cappon and James Hutton. An invitation from the President and Council of the R.I.B.A. to the President of the Institute to attend the proposed festival dinner in London on July 2 in celebration of the first general meeting of the Royal Institute on July 2, 1834, was submitted and the hope expressed that Mr. Mackison would be able to attend, and that he might be accompanied by other professional brethren from Dundee. Proposals for additions to the rules, to be decided at the annual meeting in June, were submitted, and the Council was requested to draw up proposals for the revival of rules to the first meeting of the Institute next session. The thanks of the Institute were awarded to Messrs. J. G. Orchar, A. C. Lamb and C. Ower as judges in the competition. A vote of thanks to the chairman terminated the proceedings.

DESIGN AND BUILDING.

A WRITER in the last number of the *American Architectural Review* says:—

Mr. Norton has told us what, in all honesty, we hardly needed to be told, that our modern design is lacking in fine sensibility, in repose; it is too self-assertive, too personal, too self-conscious. Now we know perfectly well that this is true. We are self-conscious in our work. It is the rarest thing in the world to find a modern building of any importance that looks, for example, as our ideal of a gentleman should look—unaffected, intelligent and unburdened with any sense of his manner or outward appearance.

There is a very rational explanation of this condition we think. We would trace it through the analogy just introduced. The man whose manner of carriage and conversation seems most sympathetic and agreeable to us is not thinking of his manner, but of us, or his subject, of the thing he is doing. His mind is centred on something far remote from the impression that he is making. It is this unconsciousness of his outward effect that gives it its peculiar charm. Put it the other way, and remember any man you know who is always thinking about the effect he is producing on you by his conversation, or his manners, or clothes, and it is easy to see how invariable is the rule that unconsciousness of self is a grace.

Every one who designs knows how much more charming is some little sketch made hurriedly for the purpose of working out a tentative idea than any drawing he is able to make from his finished work. In the first sketch his mind is on the idea itself; in the second he thinks of his drawing, and the consciousness that his drawing may be criticised mars it.

General Grant wrote his book in his plain, straightforward fashion of executive man, and produced, unawares, a great piece of literature.

Lincoln, with countless cares filling his mind, went to Gettysburg and jotted down his immortal address on the back of an envelope in a train.

These heroes of our war were not thinking of a literary greatness when they wrote. Their hearts and minds were full of issues far greater than the form their utterances was to take, and because their interest was not in their form of expression, their form of expression was full of interest. This paradox was enunciated long ago by one who said, "He that loseth his life shall find it." It receives its practical illustration in the acknowledged fact that the architects of all the most truly beautiful buildings of the world before the Renaissance were

not architects but builders. Architecture as an art did not exist, although building did. In those days builders produced architecture; to-day, architects produce buildings. We cannot begin to rank our average production with their work, considered as art. Their work has invariably that serene air of unconsciousness which is so conspicuously lacking in ours. Moreover, they possessed that indefinable perception of the shades of expression which constitutes so large an element of art. Their work, indeed, has furnished Mr. Norton with the very basis of comparison which he exercises against ours.

Now the essential point of difference between the relation the designers of those buildings had to their work and the relation we hold to ours is that they built it, whereas we only design it. Apparently it was this fact that made their design better. And we find, from what we have just been considering, that this seems only a natural conclusion. The master workman responsible for the construction of a cathedral had something to occupy his mind far more absorbing to him, we do not doubt, than the correction of details of arch mould and capital. And it was partly because of the mental discipline this responsibility entailed upon him, partly because of his familiarity with his tools and material, and the actual fall of light and shadow, that he could proportion and mould and carve the various parts of his work with that freedom from all affectation which is the crown of art. Preoccupied with the structure, stability and general rightness of his building, his expression was natural and unconscious. His conscious thought went into building, and of the mode of his expression he thought as little probably as Grant and Lincoln.

In the separation of the provinces of designer and builder, then, seems to lie the cause of the poverty and meanness of our design on the one hand and its pompous pretension on the other. We can trace the evidence of this historically. The trouble began with the rebirth in Italy of the art of old Rome—an art which we know to have been conspicuously false in principle and meretricious and vulgar in detail. Then was established the custom, that has since obtained, of borrowing and not earning an art. This vicious principle has so corrupted our integrity of mind that it is now hard for us to appreciate that such a process can only result in bankruptcy. But every natural parallel and analogy shows that it must be so, and the vacuity of our work, had we eyes to see it, adds the certainty of actual proof to the deductions of our mind.

Having thus outlined what we believe to be the fundamental cause of the degradation of architecture since the time of the Renaissance, let us consider some of the more specific phases which confront us, and which seem to offer an obstacle to better work. For it will be found in practice that if conditions are to be bettered, the initiative must come from ourselves, and the first step in the education of those who follow us must be taken in our own self-enlightenment.

One element in the non-appreciation of architecture as an art by the public is our trades unionism in charging a level price for the services of all. We claim that there is a difference in value between the work of an artist and the work of an ignorant bungler; but we give the lie to that claim when we agree together, as in effect we have, that the worth of our services shall be measured by the cost of executing our designs. This is about the same as saying that the painter of pictures should be paid according to the value of materials put into the picture. Now, whoever it was that established this ingenious and easily reckoned rule of payment, it is certainly we that consciously continue it by promulgating an authoritative schedule of charges sanctioned by the mass of the profession. In the face of this product of trades unionism, individual freedom of action is well-nigh impossible. Meanwhile it presents the most conclusive testimony that we could offer to the public that we ourselves do not consider architecture to be an artistic profession.

Bound up with this unfortunate condition are others, equally unfortunate and adverse to our working as artists. The outcome of them for the draughtsman, whose education is chiefly acquired in our offices, is a training of the worst kind.

We have suggested above that the fine perception of the designer in the times when building art was good came to him as a result of his intimate acquaintance with the material he was designing in and the conditions under which his work must be seen. We would like to develop this idea a little more fully.

There was a time when the arts as such did not exist. Before the Renaissance there were no fine arts, and in some remote time even the large class of occupations known under the humble appellation of arts (without a capital) were not set aside in a group, but were included among the common acts of everyday life. From such low and modest beginnings has the bewildering luxuriant growth we know to-day as art been slowly and laboriously evolved. Like every evolution, its principle of growth was a selection of what was used because of its practical fitness.

The primitive cup of a folded leaf gave place to the wooden bowl, and the wooden bowl to the earthen one, because of

greater permanence and fuller service. In like way the potter's wheel superseded the purely manual moulding of vessels because of its better service. The lip was formed and the bottom pointed or flared into a base for better service. If a man would claim his own, it must have some individual mark that he could recognise—some indication or token to distinguish it. And so ornament grew—for better service. And as the forms and shaping and decorative markings had their origin in the practical needs of the occasion, so each manner of working took its suggestion from the material in which the work was done. Through their lifelong bond of intimacy the material told its secrets to the artisan, and taught him how to handle it with the minimum of effort and the maximum of effect.

The fact is it is the material which develops the artisan, rather than the artisan his material. The capacities and nature of the one are inflexible and unchanging, whereas the other is easily moulded. This is another paradox. The man works to shape and mould his material, but is himself more shaped and moulded by it than it is by him. Man the savage came under the several influences of the simple materials from which he sought definite service. Little by little they worked upon him, establishing the limits of the path in which he must walk, turning him back now on the one side and then on the other from effort that would be profitless and vain, teaching him by experience the true line of progress, until, through the inherited knowledge acquired by ages of tentative efforts, he has gained a thousand highly-developed faculties to the one he had before.

Thus the artist is the product of his work in a far deeper sense than the work is the product of the artist. It was the contact with the iron which gave the Mediæval smith the power to design his beautiful work; it was the contact with the stone that taught the master builder his perfect sense of proportion in form; it was the contact with the life he expressed that gave Phidias the power to stir us to enthusiasm; it is the contact, in fine, with the real, the absolute, the natural, that makes the artist.

Old Edinburgh.

SIR,—I notice in your appreciative reference to the new part of the Edinburgh Architectural Association Transactions that you credit me with the authorship of the article on "Old Edinburgh" as well as of those to which my name is prefixed.

Will you give me the opportunity of stating in your columns that the late Mr. John McLachlan was the author of this very interesting record of old Edinburgh architects and architecture?

The earlier portion of his paper will be found in the previous part, together with a plan of old Edinburgh, prepared by me, which not only illustrates that paper, but bears as well on the articles on the city walls.—I am, faithfully yours,

G. S. AITKEN.

Edinburgh, 49 Queen Street : May 22, 1894.

Consul Smith of Venice, and Canaletto.

SIR,—Will you allow me to protest against your remarks about Joseph Smith in the article on Canaletto published in to-day's *Architect*. You say, "The English consul, Smith, was one of the earliest to perceive the artist's genius and to profit by it. He posed as a patron of the arts, but he was one of that class of dealers who are the most exorbitant, for he charged for the sacrifice he underwent in parting with a treasure." It might easily be supposed from the words that Consul Smith was degrading his office by his traffic in works of art. Now it is well to remember that at one time there was little restriction of a representative in making money so long as he did not sell the secrets of his Government. Lord Elgin was an example. It was charged against him that he induced the Grand Turk to believe that the concession to remove the Parthenon marbles was asked for by England, and was a part of the price for the protection given to Turkey. Yet the British Government made no objection about paying Lord Elgin for the sculpture, and the value was ascertained on commercial terms. Sir William Hamilton was another ambassador who bought and sold vases and other Etruscan, Greek and Roman antiquities. I am not eager to consider the commercial side of diplomacy; all I need say is there are numerous examples which prove that Smith was not considered as lowering his office when he bought pictures from Canaletto.

It is an everyday experience that painters who are glad to sell their works at any price afterwards look on themselves as the victims of those who gave them a helping hand when they were young and not famous. That Canaletto was at one time most grateful to the English consul is evident from the dedication plate he etched, and which is a permanent record of his

indebtedness to the "illustrious Joseph Smith." The consul was trusted by his countrymen not only for his probity but for his wide knowledge of books, pictures and antiquities. The unique collection of rare books which was presented to the nation by George IV., and is known as the King's Library in the British Museum, was mainly obtained by George III. through Consul Smith. Where is the young foreign artist who would not look on the patronage of so influential a man as one of Heaven's blessings? There is no record of any unfair or miserly transactions on Smith's part, and, as far as we can judge, he never concealed Canaletto's ability, but exerted himself to make the artist the "rage" in England. But, as the poet says,

Lowliness is young ambition's ladder,
Where to the climber-upward turns his face;
But when he once attains the utmost round,
He then unto the ladder turns his back,
Looks in the clouds, scorning the base degrees
By which he did ascend.

Canaletto was indebted to Smith, but when he reached a height through the help of his patron he tried to make out that, if it were not for Smith's trickery, he should have reached the summit unaided, and years before. It is not Italian artists alone who are prone to that way of paying debts.

How different was the conduct of Goethe. In 1786 he visited Italy, and as his object, as always, was his own culture, he wished to be provided with a copy of Palladio's designs to enable him to appreciate modern Renaissance architecture. Having obtained a copy he wrote home:—"At last I have acquired the 'Works of Palladio.' It is not the edition that I saw in Vicenza with woodcuts, but an exact copy, a facsimile in copper, produced by an excellent man, Smith, the former English consul in Venice. We must give the credit to the English that they at all times know how to treasure what is good, and have a grandiose manner of disseminating it." Afterwards, when he arrived in Venice, he made a dutiful pilgrimage to Smith's grave. In his letter he says:—"On the Lido not far from the sea the English lie buried, and further off the Jews, for neither race is allowed to repose in consecrated ground. I found the grave of the noble Consul Smith. To him I am indebted for my copy of Palladio, and by the side of his unconsecrated grave I thanked him for it. The grave is not only unconsecrated, but half-overwhelmed. The Lido is only a sort of dune; the sand accumulates and is blown hither and thither, heaped up and compressed. In a little time Smith's grave will be hardly recognisable." Goethe was too noble a genius to trouble himself with speculations about the profits which Consul Smith made out of the Palladio. He accepted Smith as a man who obtained a chance to do good to his contemporaries as well as posterity, and was not neglectful of it. For, as Goethe said on another occasion, "Let everyone only do the right in his place, without troubling himself about the turmoil of the world (which, far or near, consumes the hours in the most unprofitable manner), and like-minded men will soon attach themselves to him, and confidential interchange of thoughts and growing insight into things will of themselves form ever-widening circles—"

Damit das Gute wirke, wachse, fromme,
Damit der Tag des Edlen endlich komme."

Joseph Smith of Venice was not the only man of his name who toiled in that way—Your obedient servant,

ONE OF THE SMITHS.

London: May 18, 1894.

The Art Union of London.

SIR,—My attention has only just been called to a statement in *The Architect* of May 11, with reference to this Society and its recent appeal against assessment for rates, and as your paragraph contains an important misstatement of the judgment given in this case, and one likely to create a very injurious impression with regard to the Society, I shall be obliged by your inserting a correction in your next issue. Your paragraph states that the Art Union was declared to be "an unauthorised art lottery," whereas the words used by Mr. Justice Wright, as taken from the shorthand note, were, "To my mind it appears that this institution is now in substance—I do not use the words offensively at all—an authorised art lottery."

This Society conducts its operations under a royal charter granted specifically in pursuance of the Act for legalising art unions, and any departure from the provisions of that Act would very soon be interdicted by the Board of Trade. The *Times* newspaper, in their first report of the case, made a misstatement, but which was corrected in their issue of May 10.

I shall be glad of your assurance that this matter will have your immediate attention.—I am, faithfully yours,

R. W. F. HARRISON, Secretary.

[The "Note" to which the Secretary refers expressed the legal aspect of the case as far as it could be done in the briefest

terms, and certainly without any intention of creating an injurious impression. The words of the learned judge are guarded, and if litigation arose we presume they would not be accepted as a warrant that the Art Union is in every circumstance an authorised art lottery. The Council also must have a misgiving of the kind, especially after the result of the appeal case; otherwise they would hardly refer to the inaction of the Board of Trade, a department that at one time was supposed to aid in the promotion of art. If an individual were to take action against the Art Union, which we do not advise, the plea of tolerance by the Board would not be of much avail. The judgment in the recent action makes it plain that the position of the Art Union has been misunderstood, and as it possesses no privilege in respect of local rates and taxes, so on inquiry it might be found that it was vulnerable in other matters. The Council will do well to consider whether it is not possible to obtain more security, and in that way increase the efficiency as well as the stability of the Union.]

GENERAL.

The Directors of the Maidenhead Commercial School Company have selected designs for schools in competition by Mr. Stephen Salter, jun., F.R.I.B.A., of Isle of Wight and Maidenhead (Davy & Salter). The same architects have consented to act as honorary architects for the proposed Maidenhead Public Library.

The Keighley School Board have decided to invite plans in competition for a new school for 500 children and 200 infants.

The Alexandria Archaeological Society have resolved to issue a protest against the proposed submersion of the Philæ temples in connection with the Nile reservoir scheme proposed by the Irrigation Department.

Plans by Messrs. Essex, Nicol & Goodman for the erection of a meat market and slaughterhouse in Bradford Street, at an estimated cost of 48,000*l.*, have been adopted by the Birmingham City Council.

A Meeting will be held in the Mansion House to-day in support of the fund which is being collected for the decoration of St. Paul's Cathedral.

Mr. R. W. Gibson, architect, has been successful in the competition for the Clearing House Association's new building, New York, of which the estimated cost is about 300,000 dols.

Mr. W. J. Woodhouse has obtained the Conington prize for 1894 by his dissertation on the geography, topography and antiquities of Ætolia.

The British Commissioner-General has announced that the final day for receiving goods at the Antwerp Exhibition would be the 26th inst., and that any space then unfilled would be declared forfeited by the Belgian authorities.

The Design of Mr. Ernest Flagg for the Washington State Capitol, to be erected at Olympia, has been accepted. There were 189 competitors. Professor Ware, of Columbia College, the consulting architect, made the selection. The building is to be 300 feet by 150 feet, and is to cost 1,000,000 dols.

Christ's Hospital will be open for the reception of scholars on June 4, the reconstruction of part of the sanitary works having been completed.

The Annual General Meeting of the Institution of Civil Engineers will be held on Tuesday evening, the 29th inst.

Mr. E. Brocklebank has offered 1,000*l.* towards the restoration of the Radley chancel in the parish church of Bunbury, Cheshire.

The Swansea Harbour Trust have appointed Mr. Augustus Oswald Schenk as engineer to the trust at the salary of 500*l.* a year.

The "Old Antwerp" part of the Antwerp Exhibition has been carried out under the direction of M. Geefs, architect, and M. Van Kuyck, painter.

The Congress for the advancement of Christian archaeology will be held in Spalato from August 20 to 22 next.

An Exhibition of contemporary painters has been opened in Brussels. Great Britain is represented by works contributed by Sir F. Leighton, Sir J. E. Millais, Mr. Alma-Tadema, Mr. Lavery and Mr. Brangwyn.

The Bridges Committee of the County Council received a deputation of members of the art standing committee of the Royal Institute of British Architects, who desired to lay before the Council their views as to the importance attaching to the new bridge at Vauxhall as an architectural monument. The Chairman explained the numerous difficulties inseparable from such an undertaking, and having thanked the deputation for expressing its views, the latter withdrew.

The Architect.

THE WEEK.

THE removal of the houses in Poet's Corner and Old Palace Yard, in order to render Westminster Abbey more safe from destruction if a fire occurred in any of them, will be an operation which can only be regretted by the tenants. The purchase of the property was recommended by the Royal Commission that inquired into the condition of the Abbey and its capacity as a place of burial. It was intended to bring in a Bill in the present session authorising the Office of Works to deal with the subject, but owing to the facilities offered by the Ecclesiastical Commissioners and the leaseholders, it is anticipated that arrangements can be made for the acquisition of the property in a simpler way. When the site is clear, the erection of a chapel on it can then be considered under new conditions, and Mr. YATES THOMPSON may obtain a chance to display his liberality by paying for a building to shelter the remains of notabilities. It is not likely, however, that any steps will be taken for the disposal of the site until another investigation takes place.

ON Saturday last the French Académie des Beaux-Arts were occupied with the election of a member to fill the chair of the late JULES PIERRE CAVELIER. The fortunate candidate was M. LAURENT HONORÉ MARQUESTE. The new academician was born at Toulouse in 1850. He studied under M. JOUFFROY and M. FALGUIÈRE, and obtained the Prix de Rome in 1871. M. MARQUESTE obtained a third-class medal in 1874, a first-class in 1876, a second-class in 1878 and a gold medal in 1889. Among his works is a figure of *Architecture* for the pediment of the Palace of Liberal Arts, one of *Geography* for the new Sorbonne, and he completed the equestrian figure of *Etienne Marcel* which is placed near the Hôtel de Ville, Paris, and was commenced by the late M. IDRAC. Among his statues are *Perseus and the Gorgon*, *Velleda*, *Susanna* and *Galatea*.

ALTHOUGH Europeans have derived no benefit from the World's Fair in Chicago, it is to be regretted that the French Government have commenced litigation against the managers for the damage which was caused in the French section by the fire which arose after the close of the exhibition. The Americans merited to have a different sort of acknowledgment of their enterprise, for it must be allowed that in Chicago, as in the Civil War, they played for success with stakes that were remarkable. As far as can be ascertained, the exhibition cost about five and a quarter millions sterling (5,222,000*l.*). So large a sum was never expended on any of the preceding exhibitions. It was not anticipated that the money would be returned. The receipts apparently were 2,120,000*l.* from admissions, 750,000*l.* from concessions, and from miscellaneous receipts and interest 159,000*l.* A sum of more than 3,000,000*l.* had therefore to be granted or lent, and it can only be returned indirectly through the increased gains of American industries. The Royal Commissioners summarise the expense by saying that "the total outlay by the American executive upon the Chicago exhibition may be taken as about six millions sterling, of which it may be said, roughly, that three millions were earned by the Fair, two millions subscribed by Chicago and a million provided by the United States Government. Besides the above sums there were, of course, the sums granted by the various participating foreign Governments. The total of these is estimated at about 7,000,000 dols. (1,440,000*l.*)." The European exhibitions appear to be hardly deserving of comparison with the Chicago Fair. In 1851 there was a profit derived that was sufficient to buy a part of South Kensington, and yet the receipts were only 506,243*l.* From the exhibition of 1862 the receipts were 459,631*l.* The Paris exhibition of 1855 produced 128,099*l.*; in 1867 the amount was 408,530*l.*, and in 1889 the receipts from all sources, and including subsidies, reached 1,080,000*l.* Chicago may therefore claim to have set up a record which Europe is never likely to exceed.

A GLASGOW builder, Mr. JAMES PARKER, has obtained a decision which has interest for contractors, especially if it should be upheld in the superior courts. He claimed 50*l.*, or such sum as might be found due to him, from the City Union Railway Company. Large quantities of stone were delivered to Mr. PARKER by the company's trucks, and he duly settled the accounts every month. The company's agent having been dismissed for irregularities in his account, Mr. PARKER became doubtful that he was charged for an excess of weight, and having satisfied himself, brought his action. The company pleaded that the action was irrelevant, and that if the builder was defrauded they could not be held responsible. Sheriff SPENS, before whom the case was tried, does not take that view, and has ordered the accounts to be investigated so as to ascertain the exact amount of the excessive charges. He declares that where a stationmaster is entrusted by a railway company with the power of rendering and collecting accounts in connection with the carriage of goods, and he should make false statements as to the weight and induce payments to be made proceeding upon the false basis, so far as the public are concerned they are entitled to believe that the accounts so rendered are the accounts of the company and not of the individual, and for the accounts of the company the company are responsible. The plaintiff was entitled to rely on the agent acting within the scope of his authority. If the stationmaster made false returns, and in the belief they were true returns of weights builder paid carriage, the plaintiff is quite entitled to look to the company for repayment of the sums which were paid under fraudulent misrepresentations.

It was hardly wise on the part of the committee for the enlargement of St. Paul's Church, Clacton-on-Sea, to dispute the account of their architect for the preparation of plans, when the amount of it was only 79*l.* As often happens in such cases, it was necessary to get out plans that would be adapted for other works if money could be obtained for them. The committee paid 25*l.* into court. Mr. Justice CHARLES, who heard the case on Wednesday, gave judgment for 52*l.* 10*s.*, which was splitting the difference between the two amounts. His lordship also gave an opinion against the schedule rates, saying that although they had been repeatedly proved to be customary, the courts had declined to be bound by them. Mr. Justice CHARLES held that all charges by architects must be determined by what is a fair and reasonable remuneration for the services rendered in each case.

THE island of Candia, Creta, or Crete, offers one of the most tempting exploring grounds for the archæologist. The ancient traditions about the structures are likely to have had some basis of truth. Crete was the territory of MINOS, the law-giver, who had the labyrinth constructed in imitation of one in Egypt. In the history of Greek sculpture the Cretan artists DIPENUS and SCYLLIS appear among the earliest creators. The island must have been often visited by Phœnicians, the great middlemen of antiquity, and, as in other places where they came, there are likely to be many proofs of their presence. The inhabitants, however, retain the qualities which gave rise to the saying, "Cretizare cum Cretensibus," and St. PAUL refers to another by one of their prophets, who declared, "The Cretans are always liars." The Government is not of a kind that promotes truth and honesty. Accordingly, several archæologists who tried to gain a footing in Crete have gone away disappointed. The only man who stood his ground is Dr. HALBHERR, of the Roman University. He was able to remain for a few years, and became well acquainted with the island. He has been allowed to return, and it is understood that he holds a commission from the American Archæological Institute. In a short time he has succeeded in obtaining several inscriptions and some pieces of sculpture that were apparently produced after the island had become a Roman province. He has also made some progress towards insuring the safety of the immense Gortyna inscription, which is a legal edict that is of much importance to others besides students of ancient laws. It will be necessary to remove the wall containing the inscription in order to set up the masonry in the museum at Candia.

ARCHITECTURAL ESSAYS.*

LIFE is daily becoming more of a scramble, and an architect cannot help aiding and abetting those who insist on the excitement. His clients as a rule wish to have their buildings constructed or "run up" with the utmost despatch, and to gain that end they are quite prepared to sacrifice many things which in a happier or a more leisurely age would be considered essential. Where is the manufacturer who prefers refinement of detail in a warehouse to the opportunity of displaying the novelties of the approaching season to retailers and agents a couple of weeks earlier than his competitors? The majority of secular buildings are of late years built in a hurry in order to meet transient occasions, and as new churches are supposed to be demanded by most urgent needs, they have also to be completed within a definite and very limited time.

It would be considered absurd if the cottons, muslins and other gear were compared with the dress materials of an earlier time, and indeed people have been taught by sad experience to believe that modern products (not excluding sermons) are only to have a brief duration, as they are intended to serve temporary purposes. But the buildings containing the products are not allowed to be useful on those terms. They are compared with others which were intended for a different purpose, and were designed and erected with the deliberation which men considered should pertain to an architectural work.

The critics who enter on that sort of comparison are often architects, and their criticism is to be taken as an expression of discontent with their lot. It is not agreeable for a man who is eager to reflect over his design, and to wait for inspiration until he can do justice to himself, to be compelled to have it ready within a prescribed number of days or hours, or it will be useless. He knows, too, that his hurried efforts must be considered as irrevocable. Happy thoughts will come to him, and he would be glad to embody them in his design, but the builders are too expeditious in their arrangements to allow any opportunities for alterations. Need we wonder if at such a time an architect will try to console himself by brooding over the happier times in which his predecessors practised?

The interesting volume by Mr. HENRY VAN BRUNT is an expression of that discontent to which the conditions of modern practice occasionally give rise. With one exception the Essays were not prepared for publication as part of a book; indeed, one could hardly expect the murmuring of a busy architect to take that form. They all, however, have so much in common, we may easily suppose they originated from one cause, especially when we are told that "they have been developed rather from practice than from theory." Mr. VAN BRUNT, like so many architects in England, believes the architectural state is out of joint; he does not presume to say he was born to set it right, but he thinks it will do no harm if he contrasts its present state with what it was when the strains upon it corresponded with its character.

The first essay on "Greek Lines" presents that contrast as it appears from one point of view. It is wonderful that so much subtle grace should be imparted by Greek masons to blocks of stone, and apparently for the purpose of gratifying their own desire for beauty. Lines which were supposed to be straight have been discovered to be delicate curves, and curved lines baffle inquiries about their creation. The plates which PENROSE, PENNETHORNE and other inquirers have prepared are of surpassing interest, but we cannot suppose that the elaborate process that they present for the analyses of the curves was employed in setting out the contours. The Greek must have used means which are unknown to us. The volutes which the geometers and the drawing-masters teach us to construct do not correspond with those of the Erechtheum. A similar failure happens with most of the curves. In our time the majority of people are satisfied with curves of the simplest sort: a part of a circle serves as well as part of an ellipse or parabola. To many students it is, therefore, difficult to believe that the Greeks could have gone through so much trouble in the creation of curves merely for the gratification of the eye. Mr. VAN BRUNT, for instance, takes a Greek S and a

Roman cyma reversa, or semi-lemniscata, and contrasts them with one another and with the vertical line, which is supposed to be an emblem of Egyptian art. Among his observations on the Greek curve are the following:—

I have endeavoured in the representative line which I have traced to embody the characteristic grace of the delicate and elegant lines in the profiles of Greek mouldings and vases, and to present a type of the restrained and carefully-balanced rhythmic movement, the aristocratic poise, which distinguish the composition of Greek ornament. It is impossible to produce this line in that easy and thoughtless curve which Hogarth, in his quaint "Analysis of Beauty," assumed as the line of true grace, nor yet are its motions governed by any cold mathematical laws. In it is the earnest and deliberate labour of love. There are thought and tenderness in every instant of it; but this thought is grave and almost solemn, and this tenderness is chastened and purified by wise reserve. Measure it by time and you will find it no momentary delight, no voluptuous excess which comes and goes in a breath, but there is a whole cycle of deep human feeling in it. It is the serene joy of a nation, and not the passionate impulse of a man. Observe from beginning to end its intention is to give expression by the serpentine line to that sentiment of beautiful life which was the worship of the Greeks; but they did not toss it off like a wine-cup at a feast. They prolonged it through all the varied emotions of a lifetime with exquisite art, making it the path of their education in childhood and of their wider experience as men. All the impulses of humanity they bent to a kindly parallelism with it. This is that famous principle of Variety in Unity which St. Augustine and hosts of other philosophers considered the true ideal of Beauty. Start with this line from the top upon its journeyings; look at the hesitation of it ere it launches into action; how it cherishes its resources and gathers up its strength!—with a confidence in its beautiful Destiny, and yet with a chaste shrinking from the full enjoyment of it, how inevitably, but how purely it yields itself to the sudden curve. It does not embrace this curve with a sensuous sweep, nor does it, like Sappho, throw itself with quick passion into the tide. It enters with maidenly and dignified reserve into a new life which, as you glance at it, seems almost ascetic, and reminds you of the rigid fatalism of Egypt. Its grace is almost strangled, as those other serpents were in the grasp of the child Hercules. But if you watch it attentively, you will find it ever changing, though with subtlest refinement ever human, and true to the great laws of emotion. There is no straight line here, no death in life, but the composure of "maiden meditation" moving with serious pleasure along the grooves of happy change. It certainly does not seem to be merely fanciful to attribute the character of this line to a habit of chastity in thought and of elegant reserve in expression. Follow it still further, and you will find it grateful to the sight, neither fatiguing with excess of monotony, nor cloying the appetite with change. And when the round hour is full and the end comes, this end is met by a Fate which does not clip with the shears of Atropos, and leave an aching void, but fulfils itself in gentleness and peace. The line bends quietly and unconsciously towards the beautiful consummation, and then dies because its work is done.

Every one who is able to appreciate ingenuity will enjoy Mr. VAN BRUNT'S discoveries of all the relations which belong to a line that is not complex. With so much mental vision there is no doubt he would be able to find much that is remarkable in the commonest curve of a jerry-built house. But can we imagine that the Greeks were as happy as Mr. VAN BRUNT in enjoying the details of their buildings? There is nothing to show that they ever went to the curved lines for analogies. The Greeks would probably have seized on defects, and their sense of the ridiculous would have found enjoyment in any bit of a temple that was commonplace; but they were too impatient, too eager to enjoy life for meditations among tombs or masonry of any sort. EMERSON could speak about the possibility of finding the universe mirrored in a drop of dew, and that sort of intellect is apparent in Mr. VAN BRUNT'S remarks, and it becomes the more remarkable as we suppose he has had to gratify clients by displaying his speed in design at high-pressure rates.

Beautiful lines have to be subjected to laws of race, and those of the Greeks were not adapted for Roman requirements any more than for those of the nineteenth century in English towns. Mr. VAN BRUNT considers that if the lines had been familiar to the Mediæval architect, a different result would have followed. Probably the effort which was needed for the evolution of the aspiring lines of Gothic from Romanesque and Roman work would in that case have been less intense, and Greco-Gothic must have appeared as an uninteresting variety of architecture. It should not be forgotten that Greek literature and philosophy were never of much account to the churchmen who were the Mediæval teachers, for AQUINAS and the other doctors held to the matter-of-fact ARISTOTLE rather than to the sublimities of PLATO. The leading spirits of the Renaissance rebelled against that restriction, and that the Reformers agreed with them is evident from LUTHER'S

* *Greek Lines and Other Architectural Essays.* By Henry Van Brunt. Boston and New York: Houghton, Mifflin & Co. London: Gay & Bird.

thesis, "Qui in ARISTOTELE vult philosophari prius oportet in CHRISTO stultificari." Besides, how ineffective would have been Gothic if it were deprived of the power to employ the arch.

Mediæval architecture appears to correspond with Mediæval aspirations towards a better and happier world. The style is also to some extent expressive of the restlessness of modern life. But can that be said of the most faithful applications of Greek lines? There are few better examples of Ionic in London than the beautiful portico of the College of Surgeons in Lincoln's Inn Fields. But so much repose appears a mockery of the general practitioner's daily life, and of what is supposed to be the "science of medicine." It was only a few days ago that one of the medical journals, *apropos* of an application of Bishop BERKELEY'S favourite remedy, tar or creosote, announced that a new era in medicine had commenced. Can any business which is in that state, and is always liable to epidemics of new eras, be typified by a building bearing a resemblance to a Greek temple? Every congregation nowadays anticipates a change with the coming of a new rector, vicar, or pastor. Elasticity in doctrine has become a necessity. Is it suggested in the parish of St. Pancras by the copy of the Erechtheum with its rigid caryatids? The Courts of Justice, on the other hand, with all their shortcomings, at least do not appear to announce that English law is something crystallised, and formed by fixed and definite principles. As in the courts it would be hard to say what part of the buildings is dominant. A symmetrical plan is adapted for cities like Brussels and Paris, where law is codified; in London it would be an insinuation of the defects of legislation.

When therefore MR. VAN BRUNT says, "Let our artists turn to Greece; let them there learn how in our own humanity is the essence of form as a language," we would ask, Is it not wiser and better to obtain that lesson at home? Why should we pose as Greeks when we do not belong to the race? He would say the French have set us an example. They have been long engaged in the task, but they are less convinced than formerly that CORNEILLE and RACINE, with all their classicality, were wiser than the barbarian SHAKESPEARE, and the aversion to a pseudo-classicism has been one of the causes of the excesses in art which are now common in France. When MR. VAN BRUNT wrote his essay on "Greek Lines" the Neo-Grec school held sway in Paris. From that position it has fallen, and it is now believed that better models are to be found among the remains of French Renaissance. Greek lines are adapted for a people who prized architecture not only for its beauty, but for its costliness. "You can have a very good joiner," says SOCRATES, "for five or six marks, but you cannot obtain an architect for ten thousand, since there are very few of them." The hurry-scurry of modern life cannot afford to wait for the designs of a few potent, grave and reverend architects like the Athenians, and as long as it is believed that time—that is, expedition in building—is money, people must dispense with Greek lines, unless they are to be set up to rebuke their ways.

(To be continued.)

THE ST. GEORGE'S HALL PANELS.

THE four sculptured panels on the front of St. George's Hall, Liverpool, which are a gift to the city by Alderman Philip Rathbone, were unveiled on Friday last by the Lord Mayor.

Alderman Rathbone said:—My Lord Mayor and fellow-citizens,—I cannot forget that I am standing here where, fifty-six years ago, my father laid the first stone of this great temple of justice and art, of which to-day we are so proud. I cannot thank you too much, fellow-citizens, for enabling me to continue the work that my father began. The thoughts, reasonings and ideas of a nation may be expressed in its literature, the feelings and passions of that nation must be expressed in its art. If there has been one consistent passion belonging to this nation above all other nations, which is and will be recorded in history, it is the passion of justice, insisted on by that Magna Charta which guaranteed that a workman should never be separated from his tools. However unequal Englishmen may be in wealth, rank or power, in the acknowledgment of their personal rights they have always been equal to an extent no other nation can rival; therefore it is that Justice in her childhood is here represented as

a daughter of the poor in the first panel, and in the last she receives the kiss of righteousness and the crown of immortality, signifying that in the highest civilisation she will be as ever-present and as invisible as the air we breathe, and without which we cannot live. I am only too grateful that you should have allowed Mr. Stirling Lee to have expressed so worthily and in so dignified a manner ideas which, without the aid and sympathy of a great town, might have died for ever. I am proud to think that a town, which unhappily derived so much of its wealth from the slave-trade did, when it was convinced of the iniquity of that trade, send up William Roscoe to vote for its abolition; therefore I think we are worthy to have in Liverpool what I believe to be the finest temple of justice in Europe. We have to thank Mr. Stirling Lee for continuing in a thoroughly worthy and dignified way the building which had the good fortune to be commenced by Mr. Elmes, and so enabling us to say that Liverpool has known how to appreciate the gifts of genius which were placed at her service. You have now to fill up by statues the niches over the panels to complete this end of the building, and then you will have at the other end the panels and niches to fill up in order to express the prosperity and the art which are the natural result of giving every man his full rights and genius its full play. My Lord Mayor, I now fulfil the promise I made six years ago and hand over the panels to the town, and, thanks to the earnestness and genius of the sculptor, I do not feel ashamed of the way in which I have fulfilled that promise.

The Lord Mayor, in his speech, said:—In voicing the feelings of my fellow-citizens, I wish to say that we feel deeply grateful to Mr. Rathbone for his generosity in placing these panels here, and we have also to thank Mr. Stirling Lee for the description he has given of the panels.

Mr. Stirling Lee said:—My Lord Mayor, Ladies and Gentlemen,—How can a man whose art is a silence thank you adequately in words for the opportunity you have given him to place his work on this grand building? If I felt that it transmitted to you some of the delight that I have had in its production I should indeed be content. No words can express what my feelings have been in undertaking the responsibility of this work. My one anxiety was that the work should add to the beauty of the architecture and its completion. I heartily wish you would take the old proverb that speech is silvery but silence is golden. I silently give you the thanks that no gold can purchase, the feelings of a sculptor to his most generous patron. I must ask Alderman Philip Rathbone, who has so generously shown his confidence, to take silence to be the outcome of a full and thankful heart. As an artist I have come to know that the same spirit that moved the citizens of old to beautify their towns is not dead, but lives in its fulness in Alderman Philip Rathbone. How I wish it was in my power to tell you how this city of Liverpool is his very life. The bigness of the man has been revealed to me during my connection with him in this work. Nor am I likely to forget the generosity of those two citizens connected with him, the late Sir James Picton and Alderman Edward Samuelson. I should like to mention a bright artistic incident which illustrates the brotherly feeling which binds us, your younger sculptors in England, and the sympathy we have from our brother artists. This is nobly shown by the action taken by Mr. Alfred Gilbert and Mr. Onslow Ford, and by your late art professor, Mr. W. M. Conway. The two former are now at the top of the tree in their art, and the latter may truly be said to be at the summit of the mountain. I would gladly close here, but I have been told that you might like to know my thoughts on St. George's Hall, and my intention in the panels. After twelve years' close study of the building I feel it to be without doubt the greatest architectural work produced for many ages. The idea and design contained in it stamp Elmes as a genius to be placed in the ranks of the greatest men of all time. You have allowed me to fill in the growth and triumph of justice, and in doing so my life has had a desire satisfied such as has fallen to the lot of few sculptors.

Alderman Rathbone proposed a hearty vote of thanks to the Lord Mayor, and in doing so said he had received the following letter from Mr. W. M. Conway:—"My dear Rathbone,—I am just going abroad, so cannot come to Liverpool to attend the interesting ceremonial on Friday. I have watched the completion of the panels in Mr. Stirling Lee's studio with the greatest interest. I feel assured that, when all six are seen together in their places on St. George's Hall, their decorative effect will be evident to everybody. They are, indeed, from all points of view, a most interesting series of sculptures—original in artistic quality, pregnant with meaning, powerful in workmanship, and admirably adapted for the places they occupy. I congratulate the artist, yourself and Liverpool upon the completion of the first half of a most important work, destined to be for, I hope, countless generations a valuable possession to the city, and a monument of enlightened liberality."

The thanks were warmly given, and this terminated the proceedings

THE DECORATION OF ST. PAUL'S.

A MEETING, with the Lord Mayor as chairman, was held at the Mansion House on Friday last to obtain aid for completing the decoration of St. Paul's Cathedral. The authorities had announced that the fund collected in 1870 for the decoration of St. Paul's had now been practically exhausted, and it had become necessary to make a further appeal for the completion of the work. The following work had been done:—The moving, re-erecting and improvement of the organ; filling in six of the spandrels of the dome with mosaics; the reredos, credence table and marble pavement of the apse; the side screens in the sanctuary; six painted windows in the apse and two in the clerestory; the large amount of mosaic-work in the apse and the sanctuary; the sedilia; and the seat for the bishop in the sanctuary (a considerable portion of the cost of which was contributed as a memorial to the late Mr. Edward Thornton). They found themselves, at the close of the experience gained, in possession of a scheme which seemed to solve the difficult question of the decorative treatment of the cathedral, but they could not hope to complete the works for less than 100,000*l.*, and this would not complete the decoration of the aisles.

A letter had been received from Mr. Gladstone, and the Dean mentioned that the last thing which the right hon. gentleman did before the operation was performed on his eye was to write it, while the first thing he did after the operation was to inquire whether it had been forwarded. The letter was as follows:—

"I Carlton Gardens, May 23, 1894.—Dear Mr. Dean,—As one of those who joined in the movement of 1870 under Dean Mansel, I cannot but hope for the full success of your new effort on Friday next, for regarding it, together with its more obvious aims, as an effort to remove a reproach from the City of London. That great commercial community, the first in the world, is proverbially liberal in meeting all claims upon its bounty, and here, I cannot avoid thinking, is a claim not only on its bounty but on its credit. But this claim, notwithstanding the munificence of individuals, has never yet been generally acknowledged. It seems only to require being mentioned in order to be admitted. Nor can there be, I suppose, a time more appropriate for the admission than the present moment, when this noble structure, standing at the head of all the ornaments of the City, has had just enough done towards repairing the deficiencies of its interior to make more glaring than ever the necessity of doing more. There is probably not a single church in the entire country which does so much as the St. Paul's of to-day, in the way of direct ministration, for great masses of the population. Nor can I omit all reference to the striking example which has been set on this occasion by the artist who has undertaken the pictorial work. Mr. William Richmond having by his talents attained a grade in his great profession at which (I am glad to believe) it becomes highly lucrative, has spontaneously cast aside a large portion of his prospects of fortune in order to minister to the completion of this great national, ecclesiastical and religious work. Such conduct requires no eulogy in honour, fame and gratitude from posterity. But this reward the present generation of the great and munificent community of the City would also insure for itself by the simple process of seconding his example.—I remain, dear Mr. Dean, with much respect, faithfully yours, W. E. GLADSTONE. The Very Rev. the Dean of St. Paul's."

The Archbishop of Canterbury proposed the following resolution:—"That this meeting recognises the importance of completing the decoration of St. Paul's which has been so successfully commenced by Mr. Richmond whilst it is able to secure a continuance of his services." He thought they would all agree that the commencement of the work had been successful. Beauty of workmanship, beauty of design and harmoniousness of colouring were what they had been looking for and expending a great deal of money to attain for many years; but he thought few could look upon the cathedral roof now without feeling the particular work which mosaics did in preserving for ever imperishably the chief grandeur of the Christian ideas of the time. He thought that the continuance of Mr. Richmond's services, while they could have them, was exceedingly important when they thought of how many glorious buildings had been ruined by the withdrawal of the architect in the very midst of them. In Mr. Richmond they saw what it was to have been steeped from earliest years in the love of beautiful and expressive and artistic work. He had been told that when Mr. Richmond was a child eight years old he first entered St. Paul's with his mother, and that he remarked to her, "What if I were to become a great artist and were to cover this cathedral with mosaics or frescoes?" When the request was first made to Mr. Richmond to consider the possibility of undertaking the work, he at once agreed to set aside the lucrative income he was receiving for his artistic work and to accept a modest stipend which would enable him to give his time and thought to the great cathedral which had impressed him so deeply in his early years. Mr. Richmond's services were by no means limited

either to the design or the superintendence of this great work. He had always had in his mind since the idea came to him of working at St. Paul's—a most important consideration—the possibility of creating a British school of mosaic-work. He had begun in earnest in this matter, for nobody but a British workman or a British artist had touched a single thing connected with the work at St. Paul's. It was no small thing for England that a great master should stand up and say, "I will devote my time and everything I have to the formation of a new school of art and of a new industry." The expenditure of a large sum of money would be required, but he desired to point out that every farthing raised and spent on this great work would flow through natural channels in the way of wages to support the wives and families of some of the most deserving of the English people.

The Bishop of London said he felt that in appealing to that meeting he was addressing an audience that was ready to accept the appeal beforehand. He only asked them to do what ought to be done for the glory of their own building. It was the most beautiful building in the City, and he did not know any other building in all England with which he would compare it. In many respects it seemed to him that St. Paul's stood very high indeed in the list of the most beautiful buildings in the whole world. He moved the following resolution:—"That to secure the continuance of the work of the decoration of St. Paul's, additional funds are needed, and to obtain these it is necessary to seek further assistance from all who desire to see the completion of the work."

Professor Jebb, M.P., in seconding the motion, observed that under the roof of St. Paul's two different methods of mosaic could now be compared—the smooth, modern method, brilliantly represented by Dr. Salviati's work on the dome, and the earlier and rougher method as seen at Ravenna. The great idea which Mr. Richmond brought to his work in St. Paul's was the bold adoption of the older method, to the characteristics and advantages of which he referred. He afterwards testified to the reverent care which had been taken by Mr. Richmond to harmonise the decorative work at St. Paul's with the older glories of the cathedral.

The resolution was carried unanimously.

THE PHILÆ TEMPLES.

A MEETING of the Egypt Exploration Fund was held on Wednesday in last week. Sir John Fowler, C.E., was chairman. It was stated that the total expenditure of the past year was 2,140*l.*, of which the principal items were M. Naville's expenses, 380*l.*; those of Count d'Hulst, 479*l.*; tackle, &c., 37*l.*; transport of antiquities, 47*l.*; and students, 146*l.* There remained a balance of 2,160*l.* The publications of the Fund had produced 143*l.* The Archæological Survey Fund showed subscriptions 491*l.* and expenditure 1,239*l.* The Exploration Fund had advanced 712*l.* for the survey.

The Chairman said they would naturally expect him to say a few special words respecting the possible damage to the beautiful island of Philæ, and to its most interesting and picturesque ruins, by the erection of a high barrier across the Nile to secure a much larger supply of irrigation water at low Nile, and especially when several years of low Nile followed each other. In the latter events serious losses and widespread distress were at present inevitable. The only means by which provision could effectually be taken against such a disaster, and full effect given to the recent improved irrigation works in the delta of the Nile, was by the construction of a dam. Now that deficits had disappeared and the times were favourable the Egyptian Government had wisely determined to take practical steps, and had appointed a Commission to report on the various schemes suggested. These schemes had all been found unsuitable, with one exception, which was to construct a dam across the river near the Assouan cataract. The river was here of moderate breadth, and its bed was of granite. There were two alternative sites, one to the south and the other to the north of Philæ. If the former was chosen Philæ would not be interfered with, but if the latter was selected Philæ would be overwhelmed in the pent-up waters, unless some method of preservation was adopted. In either case the level of the Nile would be affected for 150 miles above the barrage. The more southern scheme would involve very great cost and risk. It was not surprising that a majority of the Commissioners adopted Philæ as the site, and so far he agreed with them. If the Egyptian Government adopted this scheme most elaborate surveys and investigations would be required before details could be worked out. It was understood that a large staff of surveyors, under a competent chief, had already proceeded to the spot to commence their studies, which would include an exact survey of the villages, the land on the banks of the river, and the ruins of the temples, which would be liable to interference. He had no doubt the Egyptian Government would proceed with the greatest care, and he would look forward to their publishing a record of the survey over a distance of 150 miles from Philæ. If it was determined to erect a dam to the south of Philæ, thus

involving no interference with the island, a great relief would be felt in Egypt and by all friends of Egypt. But if, on the contrary, there should be circumstances of cost and contingencies that inevitably compelled a decision on some point north of Philæ, the serious problem would present itself as to the best means of preserving the island and its temples. He exhibited exact plans, drawn to scale, to show that these temples were very large and important works. The drawings showed to him, as an engineer, that it would be a work of absolute certainty and of no very great difficulty to raise the temples bodily, so that they would occupy in reference to the new level of the water exactly the same place as they did now in reference to the present level of the Nile. Many of those present had gazed with admiration on this beautiful island with its temples, and had remembered its special claims to protection as having been worshipped in as the most sacred place in Egypt, and that it probably received the ashes of Osiris. The glorious ruins of the Nile valley were the records of the resources and the power of the ancients in constructive works. In recent days the resources and power of the moderns made it possible to reconstruct those temples. It could not have been done twenty years ago. His idea was to utilise some of those modern resources for the preservation of Philæ. They might safely take it that there would be no difficulty whatever in raising every temple in the island without disturbing a single stone, and in filling up the island to the new level, so that the relative position of island and water would be maintained after the construction of the dam. The only change would be an increase of beauty by the greater breadth of water round the island, and its being placed at a higher level. He still hoped that the site south of Philæ would be adopted, but if not, the solution he proposed would be a satisfactory one. The cost would only be a small proportion of the total cost of the new irrigation work. From his personal knowledge he could give an emphatic contradiction to the statement that the people of Egypt were indifferent to the fate of the wonderful ruins of the Nile Valley. He believed nothing would be more fatal to the popularity and success of the magnificent proposal to obtain a perennial water-supply than to get it by the burial of the temples in the lake which would be created. If the work of irrigation was carried out successfully the increase of the wealth of Egypt and the increase of the comfort and well-being of the people would be almost fabulous. It was the only thing wanted to make Egypt the most prosperous country on the face of the earth. He thought it would not be out of place for the members of the Fund to express to the Egyptian Government their great satisfaction with the words of the Under-Secretary of the Public Works Department of Egypt, Mr. Garstin, who had stated that any work which caused either partial damage to or the flooding of the Temples of Philæ would be considered by the whole civilised world as an act of barbarism. When that was the feeling of the Egyptian Government they might be content that that Government would be the last persons in the world to carelessly destroy or injure, or allow to be injured, the island of Philæ.

DISCOVERIES IN THE CITY.

IN digging for the foundation of the premises now being erected in Cornhill by the Union Bank of Australia some most interesting discoveries have been made. At a considerable depth below the level of the street there have been found two parallel Roman walls, with cross walls at intervals, forming a series of quaternions about 30 feet square. They stand on the original ballast, are some 5 feet thick and 10 feet or 12 feet high. They are faced with Roman tiles, and most probably are part of the same walls which were discovered some few years ago under the buildings opposite. It seems that about this spot was one of the boundary walls of the ancient Londinium. The workmen have had to cut a portion of the walls away, but found the work exceedingly arduous, it being quite as difficult as cutting through a solid block of granite. The wall is composed mainly of chalk, flints, Kentish rag and cement. Several pieces of pottery, all more or less broken, have also been found, portions for the most part of water-bottles and vases, some of which are prettily marked. No bones or coins have been turned up at present.

At the old premises in Threadneedle Street of Messrs. Prescott, Dimsdale & Co., which are being demolished to make room for new offices for the Sun Assurance Company, there has just been found, apparently under the floor of what was once one of the banking-rooms, a brick chamber or vault about 6 feet square and some 7 feet or 8 feet high, which was quite filled with human bones carefully stacked together. Among these were the two halves of a woman's skull, and, from the clean manner in which the bone is cut through, it is assumed that probably a post-mortem examination was held on the body. How the bones came to be there is at present a mystery, but an explanation may perhaps be found in the fact that many

years ago, before its removal to Moorfields, the church of St. Bartholomew (Exchange) stood on this site. The bones have been removed in cases to Ilford, and there reinterred.

THE HELLENIC SOCIETY.

AT a meeting of the Society for the Promotion of Hellenic Studies, held on Monday, Miss Eugenie Sellers read a paper on a Greek head in the possession of Mr. Humphry Ward. The head, which is that of a woman, is sculptured in Parian marble, and is in a relatively good state of preservation. The nose, however, was rather badly disfigured, though enough of it remained to enable it to be restored to its original form. After a minute consideration of the workmanship and the treatment of the hair and features, Miss Sellers concluded that the head was an original piece of sculpture dating from the first half of the fifth century B.C., or just before the time of Phidias. From several points of resemblance between it and the Aphrodite in the well-known throne of the Villa Ludovisi, she was inclined to think that they were both of the same period and the work of the same artist, namely, Calamis, and she suggested that this head, too, represented Aphrodite. In the discussion which followed, Mr. A. S. Murray, while agreeing on the whole with Miss Sellers, questioned whether the Ludovisi throne was so archaic as she supposed. The second paper was on the paintings of Panæus, a brother or cousin of Phidias, and in the absence of the writer, Mr. E. A. Gardner, it was read by his brother, Professor Gardner. It dealt with the vexed question of the exact position of the paintings which Pausanias describes as having been executed by Panæus on the throne in the temple of Zeus at Olympia.

TESSERÆ.

Perpendicular Ornament.

AMONG the ornaments prevailing in the later period of the Perpendicular style are the Tudor flower and rose. The Tudor flower is a foliated crest set at intervals upon the cornices of screens or upon tie-beams, transoms, capitals, corbels, &c. It is said to resemble a strawberry-leaf. A small and simple trefoil is frequently placed in the spaces between the leaves. A corbel in Magdalen College, Oxford, is enriched with this flower, which is rarely found in work of the fourteenth century. When used as a crest it is variously formed, but always upon a regular system. Sometimes a row of attached squares, placed lozenge-wise, their bases connected by inverted semicircles, forms the groundwork of the design. A leaf, or a conventionalised form of leaf, is arranged in each square, and often three buds, berries or other fruit are set up in a pyramidal form in the spaces between the leaves. The squares are sometimes not attached, but arranged at certain distances apart. There are several kinds of architectural roses—the simple five-petaled rose, a conventional form of the dog-rose; the double five-petaled rose, the triple five-petaled rose, roses with six single petals, and double and triple six petals. The single rose was used in the reign of Henry VI., and the double rose surrounded by rays is said to be the cognisance of Henry VI. and Edward IV. It occurs on pulpits in Worcester Cathedral and Magdalen College, Oxford. The double rose ornaments a pedestal in a niche of Henry VII.'s Chapel, Westminster. It is often used alternating with *fleur de lys*, and it is sometimes enriched by a floral wreath. The triple rose is beautifully sculptured upon the south porch of King's College Chapel, Cambridge; it occurs with the portcullis. Spandrels, particularly during the Perpendicular period, gave the Mediæval architect another field for the exercise of his skill in designing floral decorations. In the early periods they were mostly plain. On the tomb of Archbishop Theobald, in Canterbury Cathedral, the space between the arches has simply a trefoil on an upright stem. In the chapter-house of that cathedral the spandrels have sunk panels filled with diaper-work. In the spandrels of the arches in the triforium and in those of the lower arches in Westminster Abbey there is diapering. Each spandrel of a Perpendicular doorway is mostly composed of a quatrefoiled circle, having a shield, rose or foliage in its centre, and the remainder filled with foiled panels. The spandrels of the porch of King's College Chapel, Cambridge, exhibit the Royal Arms of England in elaborately-foiled circles, and in the panels the Tudor rose. During the same period the spandrels of the nave arches were often highly ornamented, as in the church of St. Mary the Greater, Cambridge. In designing ornaments in spandrels, especially of the Perpendicular period, the usual course was to insert in the triangular space either vertical foiled panels, a circle quatrefoiled, or a square modified for a shield or a portcullis. It was an easy and save-trouble system to fill up a spandrel with a foiled circle, and then to foil and foliate the spaces remaining, but to group foliage, flowers and

fruit was neither an easy nor an economical process. When plants were selected, the geometrical rule for arranging them was the same, although the result was different. The stem, if its root was not hidden by the leaves, germinated from one of the angles, and was coiled in a circular form, sending out shoots to the intermediate angle and to fill vacant spaces, and it then assumed a flowing line to the extreme acute angle. The end of a stem, as if broken off, should not be introduced. The Mediæval architects did sometimes represent foliage with such stems in crockets as well as in spandrels, but these examples should be avoided, as it is much better for the branch to grow out of the building than to appear to be stuck on. Foliage flowing from the mouths of animals, or from an unnatural extension of the tail, should not be imitated. Sometimes the latter assumes beautiful curved forms and foliage; it would, however, be as ornamental and less absurd if the animal were omitted.

The Mosaics of St. Sophia, Constantinople.

The dome, arch or conch was built with brick or stone and rendered with rough plaster to make a key for subsequent coatings. Then a strong and fine plaster nearly an inch thick was put upon it. Cartoons or drawings were made to assist in transferring the subjects to the wall, or they were drawn on the plaster itself; then, beginning with the most important part, the artist knocked out with his chisel a piece of the plaster corresponding in size to that which would be occupied by a few tesserae. He then went to the trays in the compartments of which the coloured glasses were sorted, and selected a piece of the vitreous material of the proper colour, which might be of the size of a circle 5 or 6 inches diameter and half an inch thick. To cut this to a particular shape he used a particular apparatus. Placing the piece of mosaic upon a sharp edge of iron, and striking it with an edge tool exactly plumb with the under iron, he fractured it in a direct line between the two edges. This was the later method, but an earlier one was to draw a hot iron along the line in which it was desired that the material should be fractured. Having thus the small piece he wanted, the artist took some fresh cement (made of 1 part of lime with 2 of marble dust), inserted the piece, and pressed it till it was flush with the adjoining plaster, and he could see whether more cement was wanted and how the mosaic was bedded, and so he proceeded till he had finished a face or some other leading feature, when he left off to commence in another place, allowing an inferior hand to work upon the draperies, &c. In the ancient mosaics the cement was made as above described. In the Middle Ages it was made with lime and travertine stone, and still later, where the work was very fine, and it was wished to retard the setting, lime and linseed oil were used, so that the mastic remained soft all day, and the mosaics might be eased as they were respectively bedded. There is one peculiarity of treatment which was universally observed, namely, if the artist had to execute a profile of any kind, all the longitudinal joints of the flesh would be parallel to the contour, but instead of the joints of the gold ground abutting directly upon the contour, they followed round it parallel to those of the outer flesh-colour series; the great object of this line of gold ground mosaic was to prevent interference by the joint-lines of the general ground with the repose of the heads. An inferior workman, who had his cubes of gold ground mosaic ready cut to a rough square on the surface, then put them in as fast as possible. That completed the work, and it set. Some of the mosaics at St. Sophia have a peculiar character, which M. Salzenberg observed by the aid of the scaffolding for the repairs, namely, when the mosaics can only be seen from beneath at an angle exceeding 45 degrees, the pieces are arranged with their upper edges set forward from the wall face in tiers further and further apart as the angle of vision is increased. By this means the work is saved on much intervening space, and both material and cost economised—in some parts to the extent of two-thirds of the whole. This method had also the advantage of reflecting the light at a better angle to the eye.

Materials in the Paris Fires of 1871.

Walls constructed of freestone were seriously deteriorated, the stone being destroyed by disintegration and the calcination of the limestone, and offering no further resistance. Columns detached from the walls, which had been exposed to the action of the flames present, and in consequence of this change subsequently aggravated by the action of humidity, a most curious appearance, especially at the Hôtel de Ville and at the Tuileries. The frustra of the columns, having lost their arrises, had a spherical flattened form. Rubble walls, covered with a thick layer of plaster, owing to this preservative coating resisted unchanged, and generally were able to be retained in the process of reconstruction. Walling of brick and (calcareous Silician) mill stone generally resisted better, especially in cellars and underground construction; the brick flues of chimneys remained almost intact. Wood in floors and roofs was completely consumed; but in wooden partitions, where a coat of plaster sufficiently thick was continually exposed to the

action of the fire, the wood was completely preserved. Some curious facts were witnessed. An angle post having been attacked on an upper storey, the fire afterwards extended itself in the interior of the post without gaining the external surface, which was covered with plaster, so that the post, remaining for a long time in its place, had the appearance of a pipe, the interior of which had been hollowed out by the fire. Oak lintels covered with plaster, on the other hand, resisted without injury the flames which traversed the bays of which these lintels formed the upper part. Iron did not resist the action of fire. Where it was not consumed like wood it underwent twisting and contortion, deformation and sometimes exfoliation, which rendered it unfit to be used again, and of which numerous and fantastic examples were seen, especially at the Palais de Justice, the Hôtel de Ville and the Théâtre Lyrique.

Handicrafts in India.

The typical Hindoo village consists exclusively of husbandmen, but as husbandry and manufacture cannot exist without each other, the village had to receive a number of artisans as members of its hereditary governing body. But they are all "strangers within the gate," who reside in the village solely for the convenience of the husbandmen on a sort of service contract. It is a perpetual contract, but in the lapse of 3,000 years the artisans have constantly terminated their connection with a village or have had to provide for sons in some other place, and they at once sought their livelihood in the towns which began to spring up everywhere round the centres of government and of the foreign commerce of the country. It is in this way that the great polytechnical cities of India have gradually been formed. Community of interests would naturally draw together the skilled immigrants of these cities in trades unions, the bonds of which, in India, as was also the case in ancient Egypt, are rendered practically indissoluble by the force of caste. We learn from the Bible that already in the earliest time among the Hebrews numerous trades had developed into separate callings, such as the goldsmiths, braziers, locksmiths, carpenters, masons, potters, weavers and fullers; but it is not until after the Captivity that we find trades unions flourishing among the Jews who had settled in Egypt, the land of caste. In the Jews' synagogue at Alexandria, which was so large that the word Amen at the end of each prayer had to be signalled by the reader to the vast congregation, all the different trades unions sat apart from each other, and the workers in gold and silver, the copper-smiths and braziers, the nail and needlemiths, the potters, carpenters, masons and weavers had each their appointed seats. The spirit of trades unionism thus spread from Egypt among the Jews into Palestine, who at last carried it with them into every country in Europe. In India these trade guilds have also existed from the very beginning of Hindoo civilisation. In the nineteenth chapter of the second section of the Ramayana—or Ayodhya-Kanda—"Scenes in the Ayodhya," the inhabitants of that city are represented as going out in procession with Bharata to seek Rama in the order of the trade guilds—jewellers, potters, ivory workers, perfumers, goldsmiths, weavers, carpenters, braziers, painters, musical instrument makers, armourers, curriers, blacksmiths, coppersmiths, makers of figures, cutters of crystals, glass makers, inlayers and others, with the chief of a guild bringing up the rear. It is just such a list as might be prepared from a census return of the inhabitants of Ahmedabad in Western India at the present day.

Colour in Churches.

Colour may be applied to architecture in various ways. First, in mere lines and plain tints to bring out the architectural features of the building, and to give emphasis to its important points such as capitals, arcades, windows, doors and string-courses, or to make sculpture stand out from its background in stronger relief. Again, colour may be applied in ornamental forms and various colours, so as to add enrichment to the edifice. For instance, a string-course or capital may have such ornamental features added in paint as we often find sculptured upon them. Of course, sculptured ornamentation is the better of the two, but sometimes pecuniary resources do not admit of the expense. Again, colour may be used to supply the effect of absent architectural features. For instance, a window which has no label moulding may have the same emphasis given to it by a line of painting round it, and in the same manner the effect of a great many other architectural features may be supplied by painting. Another important branch of the subject is the application of colour in order to heighten the effect of good proportions, or to diminish and relieve bad proportions. For instance, if a building is too low, it may be heightened a good deal in appearance by multiplying vertical lines on the walls and by putting a receding tint on the roof. Or, on the other hand, the apparent height of the roof may be reduced by a dark colour on the ceiling, and the height of the walls may be diminished by horizontal lines. Sometimes a building appears bare and cold for want of colour, especially if its furniture is meagre and colourless; while, on the other hand, a small church may be spoiled by a

too rich and elaborate style of decoration, especially if it is overcrowded with furniture. Again, a different tone of feeling may be imparted to a building by a different style of decoration. For instance, in churches in the Perpendicular style a large portion of the wall space is occupied by the windows. In this case, of course, stained-glass will be the principal feature of the decoration, and the wall will simply be a framework to display these brilliant translucent paintings. Here we need only add a few lines of painting to carry the colour into the architecture, and the effect of the church will be light and brilliant. Take a church in the Decorated style, which has smaller windows and more wall space, and we shall produce a very different tone, according to our mode of treatment. We may simply paint the walls with a series of historical subjects in bold outlines on the buff-coloured plaster, or we may colour the walls red, and put paintings upon it in other tints; or we may make the walls slate colour, and diaper it with dark red fleur-de-lys, and we shall get three very different effects out of the same architectural outline, and all of them very different from the effect of the light and sunny Perpendicular church.

Northumbrian Fortifications.

Whilst Edward I. was building castles in Wales, he was also at the same time directing the erection of castles and pele towers in Northumberland in great numbers, to keep out the aggressive Scots. He seems to have planted churches and pele towers in such strategical positions that it would seem as if some of the larger ones were put out as outworks, to be kept by men who were able to defend them until obliged to fall back on the neighbouring castle. Throughout the whole of the county there are regular strategical lines of defence. The castles were exceedingly numerous. At the same time that this splendid system of fortification was being carried out, the religious work seems to have been going on in the same great scale. The Norman church, beginning with Lindisfarne itself (the abbey church), had generally its apse. Nearly all these churches seem to have been elongated at this time. Even the priests had towers; their vicarage towers, their houses and their churches being alike fortified. There is a remarkable instance of one at Ancroft, on the first line of strategical defence. In these very disturbed times it was necessary to cut the church in half, and to erect it in conjunction with one half a pele tower. In another district, where the Scots were frequently making raids, are also very strong towers, the doors opening externally and on the church side. There is a popular belief in Northumberland that these towers were used for the people to fly to in case of attack; but that instead of the bolts being on the inside, as they would have been in that case, they are on the outside, and therefore the conclusion can be drawn that they were used for keeping the Scotch prisoners in. The Welsh and Northumbrian examples are alike adapted to their respective sites and to the materials of the respective districts. The castles of Northumberland are, however, finer than those of Wales in respect of material and masonry. Carnarvon Castle, for instance, is built of the shaly stone of the district and of small blocks, while in the castles of Northumberland immense blocks of stone were used in their erection. In Elizabeth's reign a survey was made of the existing pele towers, which led to their being put in repair, and to a great many more being built. The present remains of these military buildings are very considerable, but of course they have been much mutilated. Numbers of pele towers have been built up and used as farm-houses, and very few of them are now existing intact.

Early Brickwork in Rome.

Suetonius, in the life of Augustus, tells us that that emperor boasted that he had found Rome of brick and left it of marble. We must not take this expression too literally, but merely as a description of increased magnificence. The words attributed to him by Dion that he had found it of earth and left it of stone are nearer the truth if we suppose the term "stone" to be applied to all materials of a durable nature, as that of "earth" would certainly imply what was soft and easily perishing. The expression of Suetonius has been taken as the literal description of a fact; but of the monuments remaining known to be prior to the time of Augustus not one is of brick, while on the contrary, from his time downwards, brick was evidently used in the greatest abundance. Vitruvius, who certainly did not publish his work before the time of Augustus, is diffuse in his account of unburnt bricks, but says nothing about the formation of burnt bricks, which seems to prove that they were not then in common use at Rome. He proceeds to state that very good and durable buildings may be made of burnt bricks, and cites as examples several buildings in old Greece and in Magna Græcia. Another circumstance which indicates that bricks were little used at that period is found in his account of *pozzolana*, *pulvis puteolana*, which he describes as an excellent material for building, and as found about Baia and Mount Vesuvius, while in fact this substance is very abundant about Rome, and nearly, if not quite,

universal in the ancient brick and rubblework there. If, however, there are no brick monuments remaining which date certainly before the time of Augustus, there are many such which have been supposed to be of republican times. The Circus Maximus is attributed to Romulus, and some brickwork may be observed among the trifling fragments which are shown as its ruins, but as no one can believe that these are of the time of Romulus, we may as well suppose them after, as before, that of Augustus, especially as the work is of the same nature as that of the Palace of the Cæsars just behind it. The earliest aqueducts were of the time of the republic, but these form a curious lesson against the early use of brickwork, although sometimes quoted in its favour. The Temple of Saturn is also said to be ancient, but whether the lofty brick wall just by the arch of Constantine be a part of the temple, and whether, if it be so, the temple was not rebuilt under the emperors, are both disputable points. It exhibits an abuse of the use of arches, which in this example occur in the solid of the wall when there are no openings below, or none which at all correspond with the upper arches. Such an abuse does not seem likely to have been introduced very early, yet we find something of it in the Pantheon, as has been already noticed. Another edifice which pretends to an early date is that usually called the Temple of Rediculus, built to commemorate the retreat of Hannibal. But Hannibal, according to the antiquaries, approached Rome, not in this quarter, but in the neighbourhood of the Porta Salaria, and such a temple would probably have been built near the spot where he advanced nearest to the walls. The present building is in a valley far from the old circuit of the city, and not at all suited to a reconnoitring position, and the character of the work does not announce an early period of the art of building or of brickmaking.

Kant's Aesthetics.

The doctrine of aesthetics which Kant propounded may be simply stated. The beautiful, he believed, had no real existence in nature, nor is it capable of definition by a single formula. It is a harmony arising from an unknown cause which we place in nature. The pleasure of taste consists in the enjoyment of the harmony between the free play of the imagination and the laws of the understanding. The sublime is the struggle of the imagination to grasp the vast in quantity or power, awakening pain from the sense of limitation, but counterbalancing that pain by the higher pleasure of reason, as it tends at the same moment towards the infinite, so that the discord is merged in purer harmony. What this harmony of the faculties is, is not explained; and in spite of many ingenious efforts Kant's critical deduction of the validity of general principles of taste, as opposed to individual caprice, ends in little more than an appeal to the uniformity of our common nature.

Stoneworking in Athens.

It appears that the Athenians worked the marble to an even, but not a very smooth, face with a toothed chisel before they placed the blocks in the work, and that they afterwards went over the whole exposed surface and finished it to the greatest smoothness and nicety, but without polish, taking off in this operation about one-fifth of an inch; and this has been the practice on the horizontal as well as on the upright surfaces, for the columns of the Propylæa are sunk in to about that depth below the general level. The place intended for their reception was sunk before the lower cylinders were placed, and lest any inconvenience should arise from the wet remaining there before the building was completed, a small channel has been cut from the recess to carry off the water. In the steps the adjoining faces are carefully finished at the internal angles, but both are left rough at the external angles, by which means the accidents and wear which take place during the execution of the work would rarely be of any consequence.

Straight Avenues in Public Gardens.

However pretty the winding walks of our English gardens may be, they are not at all suited for a place of public resort, where any impression of magnificence is intended. They never show the people, which is a point of great consequence. The disposition of the objects in straight lines has in itself an imposing, or to use a term more English, an impressive effect, but this has its limits, and not very extended ones. The too great length of the line makes the individual parts appear little, and the mind is not satisfied with the general impression of sublimity, unless it find the character supported by the objects in its immediate neighbourhood. Beyond a certain point almost any additional length is nearly lost, and, in proceeding along it, we feel its want of variety, without any compensation. If a man were placed at the point where two narrow avenues meet, one of them a mile in length, and the other two, he would not readily distinguish the difference. By extending the line too much, also, in places of public resort, it becomes impossible to fill it with people, and this deficiency is more sensible than the length of the avenue.

NOTES AND COMMENTS.

WE may expect that a new opening for young painters will shortly be available in the decoration of Board schools. A few days ago a deputation from Manchester, but representative also of other districts, waited on Mr. ACLAND at the Education Office in order to persuade him to make arrangements which would enable children to visit museums and galleries of art. It was recommended that attendance there should count as attendance at school. It was also suggested that a small collection like those distributed by the committee of the Manchester Art Museum, and costing about 100*l.*, should be provided for groups of schools. Mr. ACLAND probably surprised the deputation by his desire to do more. The Education Department, he said, had tried to improve the condition of schools in various ways, among others by providing playgrounds and large central halls. Much opposition had been excited. He considered that schools should have pictures, and not on a small scale. The upper portions of the walls might be adorned by a fine frieze. There ought also to be illustrations of historical scenes and representations of natural objects of a larger size than had been attempted. Works of those classes could be produced by artists at a moderate cost. This scheme of the Vice-President will gratify artists. But it would be hard if the painters are expected to execute wall-paintings for sums that will hardly pay for the colours. Although the authorities in Paris can command the services of artists on exceedingly economical terms, they have been able to obtain no more than a few friezes for the schools. The officials of the Department would not sacrifice an hour of their numerous holidays for the benefit of the schools, and they have no right to expect a sort of heroic self-sacrifice from painters. If pictures are employed as aids in the instruction of the pupils, the artists should receive the value of what they supply like the producers of other materials. Mr. ACLAND proposed to introduce provisions in the next Code which would tend to the establishment of school museums.

THE relations between the Hanse Towns and England reveal that German competition was turned to account six centuries ago, although often treated as an evil by English traders. The Hanseatic League was an early example of co-operation and assurance. At the present time it is necessary to obtain an armed guard in some parts of the East; in the thirteenth century it was indispensable in Europe. Hamburg, Lübeck and Bremen deserve the credit for perceiving that it is not wise for traders to look on one another as enemies, and it is more economical to pay armed troops that will insure constant protection than to meet the demands of land thieves and water thieves. The merchants knew that force must be met by force, and the provision of the League to meet emergencies is seen in the equipment of a fleet of 248 vessels with 12,000 soldiers in order to vindicate commercial rights in Denmark. The importance of London was shown by the establishment of a factory or emporium in the City. Prior to the existence of the Hanseatic League, German merchants had gained a footing in the City, and possessed their Gildhalla Teutonicorum. To the League probably their privileges were transferred. The Steel Yard, or Steel House, at Dowgate belonged to the League, as well as another in Boston. The kings of England found it was advantageous to make concessions to the foreigners, and to give them monopolies; but the citizens could not understand the arrangement, and at the close of the fifteenth century the London apprentices attacked the stores of the Germans. England was then unable to compete with the League, and the only way to weaken its grasp on the country was by supporting a rival body that was created among the Flemings. As a consequence the League endeavoured to regain power at any cost, and in doing so committed some errors, which were punished by a deprivation of privileges. The contests between the rivals afforded an opportunity for the creation of English merchant adventurers, who by their audacity were able not only to compete with their rivals but to venture on more distant voyages. The German traders undoubtedly exercised an influence on the art of this country by importing foreign examples, and in that way

they supplemented the efforts of the ecclesiastics. They taught England, for although it was their interest to confine the industry of this country to wool-growing, the preparation of leather, and the obtaining of lead and tin, they could not suppress the inclination of the people to imitate the goods that were imported. It is also not unlikely that the foreigners were unable to monopolise all the export trade, although it was felony to compete with them. The religious Orders could do many acts that were not tolerated in laymen, and if English products were not unknown abroad, we may assume that the monks were the agents or middle-men.

THE speech which Lord ROSEBURY delivered at the banquet of the Royal Academy is likely to serve the cause which *A Beautiful World* advocates—that is, the checking the abuses of public advertisement. The third number of the journal has enough in its pages to warrant the belief that the Society is gaining a stronger hold on public attention. Many facts are recorded of a nature to inspire a crusade against the license which sacrifices the public interest to individual greed. One case mentioned by Mr. WATERHOUSE is sufficient evidence of the indifference to scenic interest which appears to be a consequence of the Governmental system of instruction in art. It is that of Durham. Mr. WATERHOUSE says:—"The interest and beauties of the place seem concentrated when seen from its two old bridges. Especially is this the case from the lower bridge, whence the view of the river is almost unique in its quiet loveliness. This, one would suppose, hallowed spot has been selected by some one—I will apply no adjectives, however tempted—for the erection of an enormous hoarding of an apparently permanent character, stretching from the houses on the right bank across the gardens which separate the houses from the river, down to, if not beyond, the water's edge, and so shutting out this view—this view unique in its loveliness—from the first part of the bridge, as you approach the town from the railway station. The hoarding, it is needless to say, is covered with the most vulgar and hideous of posters, so disturbing to the mind and eye as to render the subsequent view (but not the best view: that is obliterated) in great measure unenjoyable and unenjoyed. The other bridge is disfigured in the same way, but not to the same extent. The matchless panoramic view of the cathedral, castle and wooded slopes seen through the smoke curling from the crowded dwellings of the town below, and which used to rejoice the heart of the traveller by rail as he approached the city from the north, is now marred by the huge advertisement boards of the local tradesmen, set up clearly with the intention of catching the eye of those on the look-out for the mouldering beauties of old Durham, and giving them in place thereof something up to date to look at, and really worth their attention." Surely, adds Mr. WATERHOUSE, no object lesson could more effectively show the absolute necessity for such a Bill as Mr. BOULNOIS and others are trying to pilot through Parliament, and which would preserve for the public in general the views which are not the property of the tradesmen or of the ecclesiastics of Durham.

FRENCH architects are aware that no advantage can arise to them from exhibiting drawings in the Salon, and consequently modern work is always inadequately represented. This year, as on former occasions, the Médaille d'Honneur has been awarded for one of those studies of ancient buildings in which the French excel. It is, however, a study that has excited extraordinary attention. M. GEORGES PAUL CHÉDANNE had made a name by his discoveries in the Roman Pantheon while he held the Prix de Rome. Having sent a memoir with drawings of the building to the Salon, it was inevitable that he should obtain the highest reward that his brother architects could bestow. Accordingly at the first balloting M. CHÉDANNE secured forty votes, while his four competitors obtained only eleven between them. In the sections of painting and sculpture, it was found impossible for any artist to attract a sufficient number of votes. M. LUMINAIS was the nearest to success among the painters and M. CARLES among the sculptors. The medals are, therefore, withheld in both sections.

The Architect, June 1st 1894.

VILLA RESIDENCES TO BE ERECTED NEAR SWANSEA.

THESE sketches are of villa residences to be built shortly near Swansea. One pair has already been erected. The material employed is to be red brick, with Bath stone quoins, the roofs covered with red Ruabon tiles, and the external woodwork painted a dark chocolate. The whole of the work will be carried out from the designs of Messrs. WILSON & MOXHAM, architects, Swansea.

TOWERDENE, BRISTOL.—DRAWING-ROOM.

THE ARCHITECTURAL ASSOCIATION.

THE closing meeting of the session for 1893-94 was held on Friday evening, Mr. E. W. Mountford, president, in the chair, the proceedings being opened at eight o'clock.

Messrs. R. C. Neat, P. A. Lamb, L. Sage and P. R. Nathan were elected members.

The A.A. Travelling Studentship, it was announced, was awarded to Mr. C. C. Brewer.

The House List for the following session, as elected, was read out:—

President.—E. W. Mountford.

Vice-Presidents.—A. B. Pite and F. G. Hooper.

Hon. Treasurer.—H. W. Pratt.

Hon. Librarian.—J. W. Stonhold.

Hon. Secretaries.—F. T. W. Goldsmith and Banister F. Fletcher.

Committee.—W. D. Caröe, J. Begg, E. S. Gale, F. R. Farrow, P. Waterhouse, E. Woodthorpe, G. H. Fellowes Prynne, Theo Moore, W. H. Seth-Smith and Owen Fleming.

Hon. Solicitor.—W. H. Jamieson.

Hon. Assistant Librarians.—C. H. Freeman and E. W. M. Wonnacott.

Hon. Auditors.—G. A. Lansdown and E. H. Sim.

Assistant Secretary and Registrar.—D. G. Driver.

Mr. BOLTON read the following paper on

The Practical Side of Travelling.

Mr. Bolton said:—In deciding on any proposed tour a certain amount of previous study is generally advisable, and is to be obtained either from those who have been there or from books. As to books, it is very annoying on your return to find that you have failed to see some well-known example in some place you have visited, and of which you have seen drawings in some book. Many illustrations of old work are sensational in character, and sometimes positively misleading, but have a value if you have seen the thing itself. The best plan of study to adopt is to arrange your notes under the names of towns, placed in alphabetical order, putting down the work of all styles, the name of the artist, and the description of drawings. These notes are best on foolscap sheets of paper which can be pinned together and taken with you. You will soon be able to judge what is worth an effort to see and what is not, according to the credit you assign to the artist after seeing a few examples.

The one indispensable book is a guide-book of the latest edition and the best repute, however dear, as information is money in travelling, and a mistake in making an excursion, or choosing an hotel, would easily cost double the price of any guide-book, to say nothing of the saving of tips to local touts, rendered unnecessary by good maps. For Italy Baedeker is best, for Spain Murray, and for France Hachette, and I specially recommend the Departmental Guides of the latter, which are very useful for indexes of all that there is of interest in each town or village of the Department. Calling on people is not always successful in the way of obtaining positive information on points of detail. "Oh, you know, you just take a bag, and go right south, and come back by degrees," being the usual style of friendly advice. As to going direct south when on a long tour, there is much to be said either way. One reason against is that it is not always convenient to start so early in the year, and another is that you are translated into a new style of work which has no direct bearing on your own; whereas if you go by degrees through France you pass through districts full of work which resembles but is better than what you are doing at home, and naturally you can get to work on it at once. Moreover, when you do arrive south, you have acquired some skill in drawing, and have learnt something of the later results and meaning of the earlier work which is met with further south. It is, of course, a question of season and climate which you must look into. Egypt is visited in the winter, Greece in the early spring, Rome is left after Easter, Florence at the end of July, and so on. Spain can be visited either in autumn or spring, and a winter in Seville may be most

agreeable. As to the countries to visit, Belgium and Germany are good for brickwork and small buildings allied to our own; France should make you logical, Spain critical, and Italy enthusiastic.

Programme is the great feature of French work, the logical following out of certain ideas, excluding others considered as non-essentials. Spanish work invites criticism by the dash with which the work appears to have been done, for form, outline and programme are less considered, and things are often either masterpieces or absurdities. In Italy you will be roused to enthusiasm, because there you will see good work of all styles and the early origins of most subsequent developments, as well as the acknowledged masterpieces of all the three arts. The subject of to-night can only be useful if treated with a detail which has a large element of the ridiculous, but I am not afraid that you will fail to perceive that side of the question. However, to begin with the question of luggage. I never knew any one who took too little, but some who would have been glad to send half theirs home again. The easy manner in which the would-be traveller dismisses the subject previous to departure is in amusing contrast to his sentiments a few hours past the Channel. I had once to use all my influence to prevent a friend coming out to me in Italy, plus a portmanteau, but he candidly owned, on arrival, that no sooner had he arrived at Calais than he was thankful to have only a Gladstone. One reason for this luggage question, which it would take too long to examine in detail, is that the heavy luggage is registered, and hence there are nothing like the numbers of porters at the stations that we have. In making a change, or getting into a train, you will probably have to rely upon yourself, and it is of the first importance to be able to carry your goods yourself, at need. This condition is the determining one in all points of luggage. Registration is fallacious, because, first, it involves arriving early at the station, the process ceasing ten minutes before the train goes; consequently there is generally a great crowd at the luggage barrier, and it is most annoying to have to be waiting about for your turn, when you want to be securing your place in the train. Secondly, it involves waiting at the other end, as the process of delivering the luggage does not commence till the train is gone and is often very slow, as in Paris, where, I am told, three-quarters of an hour is a common time to wait. Hence, if you had nothing registered you would have been off, and arrived in your hotel in the same space of time. Finally, you can only register as far as the ticket goes; luggage above a certain weight has to be paid for, and in some countries no allowance is made at all. Assuming, then, that nothing larger than a Gladstone is admissible, the next question is number of inches. Here the Indian mail gives a clue. The mail through Italy has a limit of 20 inches by 10 inches by 12 inches, and I have had a 24-inch taken to the van. The same 24 inch, I may add, I was only too glad to get rid of later on for a 20-inch, which I consider the largest size necessary even for a year.

So much for No. 1; next, as we are architects, comes the question what size board shall we take. Finally, I decided on a half-imperial, which is really an excellent size. I then had a case made of waterproof canvas bound with leather, opening the long side, with two straps and two buttons for the flap. This case is best with a flat, light iron bar along the top to attach the handle to, as otherwise you will find that the flap will pull out of shape. Have this case wide enough to take the half-imperial board (in a 2s. 6d. portfolio with T-square, two set squares and 12-inch scale), a stool that will fold up flat, a roll of lining-paper and an easel. 1. The board.—This you will find best without ledges, but framed with steel in the thickness, as made by Stanley for abroad. 2. The portfolio.—This is useful to carry about in the street, as it excites less attention, and also to hold the drawings as you complete them and the paper you still have to use. 3. The T-square.—For abroad the extra cost of mahogany is well worth while. The great problem is the length, and after trying both ways, I advise you to shorten it, so that its total length is that of the board. It is of course sometimes a nuisance that it will not reach the edge of the paper, but it is still worse to carry it about projecting in a dangerous manner outside the portfolio. It is also a troublesome thing because of the thickness of the short arm, and I think the best thing to do is to buy one large or two smaller sketching-blocks, which will make up the level over the rest of the board's surface. 4. The drawing-paper.—Take, say, six sheets imperial (cut in half) of hot-pressed and the same of 90-lbs. cartridge, with some cut-up tracing-paper and a roll of lining-paper; this latter should be the best, for the common tears easily and the other is only 10d. a roll. 5. The easel.—This is a matter of opinion, but personally I find it very useful. The 3s. 6d. sold at the stores, which folds in a very ingenious way, is a good one to take, and you might have it reconstructed to fold into three, as then you could stand to it at need.

That completes our second package, and is of course only necessary if you are going away for three or four months. If for less time, the third that I am about to describe will be

sufficient. This is a bag or case of canvas, in two thicknesses, and waterproof, made by Pontifex & Wood (next to Victoria Station), for 18s. 6d. It has two divisions, one of which will take a quarter-imperial board and a portfolio, as before described, while the other will contain your things for a stay of one or two nights. It has, as before, two straps, with a handle and buttoned flap, and also loops, in case you prefer to carry it as a knapsack. It should contain (1) a water-colour case holding a short box of twelve paints, a small water-bottle and a pocket for tubes of colour; (2) a 33-inch tape and a small ball of twine, with a lead plummet, for measuring greater heights; (3) a short spirit-level, most useful in getting certain heights, as of bases, &c.; (4) a pair of callipers of wood opening to 2 feet, useful to take the diameter of shafts and other things otherwise very troublesome to measure; (5) a pocket-case of instruments; (6) a box of twelve pencils, B. S. Cohen F being the best for all-round purposes. So much for the architecture. Then a hand-size hair-brush, short comb, razors, strop, soap in case, short clothes-brush, small box of matches and flannel night-gown. You will also find that you can get two white shirts, collars, and a pair of socks in the other division on occasion. The reason why you will want a quarter-imperial board as well as a half is that the half is mostly for use at the hotel for drawing out what you have measured, and, secondly, that there are many short excursions of one to two nights to be made from a centre-point where you would leave your other two packages. Consequently I consider this No. 3 as indispensable in any trip, short or long.

Now for the fourth package. This is a rug, coat, umbrella and two measuring rods in a case, made up into a roll with rug straps. In luggage the thing to aim at is to have only the absolutely necessary, and what occupies space are generally things which, if we exercised a stricter supervision, we should leave behind. After a time you will know exactly what you want, and you will be able to get ready for a journey at a few hours' notice, and yet go away without leaving the indispensable behind. After luggage, the question of money is of the first importance. It may govern your route to such an extent that will surprise you, and your stay at any place may be either cut short or made unduly long by the difficulties of obtaining supplies. Having tried several plans, I consider, on the whole, that Cook's 5% or 10% forms are better than letters of credit on a private bank, simply because their list of agents is more complete, and contains the places you most want to visit, whereas the agents of the private banks are mostly at modern centres of commerce, which are not what you travel to see. At your bank you will be told, probably with a patronising smile at your ignorance, that their credit notes can be changed anywhere, a pious delusion which one wishes they might have to experience for themselves. Not only will you experience a most distrustful reception in tendering such paper at other than the accredited agent's, but the branch office even of a credit society, many of whose other offices are given in your letter of indication, will decline to pay unless the name of the town where their particular office is situated is given in the list. This sounds incredible, but has happened to me more than once. Consequently, study your letter of indication, and note the towns having agents which you will pass, and arrange to take in your supplies at intervals. Moreover, in France, out of the larger towns, and sometimes even there, the banks are very shy, and raise great difficulties if your papers are not exactly correct. Consequently, it is a very good plan to go to the bank soon after arriving, so as to secure that you will be able to command your money, and if there should be any difficulty you will have time to write to a head-office or to London in order to overcome it. Remember that you will be absolutely helpless if you have no money abroad; the smiling countenance of your *maitre d'hôtel* will become black as night, and everywhere you will find yourself suspected. Happy, indeed, you will be if you find some countryman who will risk a loan to carry you to some other town. And so, if you meet any other Englishman in such a plight, endeavour to assist him, as you hope to be assisted some other day. If you decide on private-bank letters of credit, observe whether they are payable at sight or not, because I have had some at seven days' notice, which made a local office propose that I should wait twelve days before I received the money, being the time to write to Paris, seven days' delay, and time to write back. A very cheerful prospect if you should be in an uninteresting place. You will probably stay longest in small places, where English notes are almost unknown, and the plan of carrying five-pound notes, which may answer in Italy in such towns as Pisa, Genoa, &c., will be disastrous elsewhere. A good hint I can give you is to carry a few sovereigns in a watch-purse as a reserve, as, at a sacrifice, you will, I think, be able to change them anywhere. Having your letters of credit all right, and having found the agency, you are in presence of a difficulty, and that is to obtain the full value of your money. Your paper states that you are to be paid in the local currency to the full value without deduction. Moreover, as you have paid in gold, and the notes are payable in gold at London,

there is a profit to be made on the exchange, and you are entitled to the market quotation of the day. Consequently, in France you ought to receive 25 francs to the pound, plus a premium of 3d. or 4d., according to the market, but which generally amounts to 2s. 6d. on 10l. Now, as the agents can always wait a rise, there need be no scruple on your part in exacting the full value of the day on the plea that they are entitled to something, as you may be certain they will not lose; in fact, I doubt if you will ever get your due. I can, I regret to say, only recall one agency where I have received the full, without asking even in the most reputable houses, though I can remember many battles on the subject. In fact, I confess I have got tired of fighting, and have now and again submitted to the loss, and even to an absurd deduction for receipt stamps. As many of you are men of war, you will do a good service to the weaker brethren by insisting on your rights, and may also flatter yourselves that you are asserting the superiority of English currency. Of course, in Italy, Spain and countries with bad finances you will get very much more than 25 francs to the pound. As I said before, it depends on the market.

Before you start, change at Charing Cross, say, 1l., so as to be able during the journey to pay for goods, porters, &c., in local value, as they will only accept English silver at a loss; and do not, by the way, take English 2½d. stamps with you to send home your letters with, as sometimes happens. In Italy and Spain at present there is practically no gold in circulation, but as the paper notes have a forced currency that will not matter. You must take your chance as to these notes, for you can hardly hope to know good from bad without much practice. With regard to the amount you must take, the expense of travelling is no doubt always increasing, and in estimating regard must be paid to the length of your tour and the plan you have in view. Sight-seeing travel is the expensive method, and the further east you go the more it is so. France is dearer than Italy, which is the cheapest country I have been in. A short tour is also much more expensive relatively, because the initial price of the ticket out raises the average daily price. You ought, especially on a first tour, to keep exact accounts and to average your expenditure from time to time, because you thus learn what constitutes the chief expense in travelling and how you can best reduce the average. It is difficult to compare the relative expenditure of students, because everything depends on the style. You can spend any sum, as some Americans who get through extraordinary amounts for what they do and see. Long stays have an important influence on the average, because such items as hotel tips, porters, buses, sacristans, &c., which bring up the average enormously, when moving about rapidly, become relatively unimportant, and of course you can make better terms at the hotel. Well, subject to these considerations, here are some figures of probable cost:—Nine months, extending as far as Athens, 150l.; six months, France and Italy, 100l.-110l.; three months, 60l.-70l.; two months, 50l.; a month, 25l.-30l.; three weeks, 20l.-25l., &c. These figures involve comfortable travelling, second-class on through journeys, good and fair hotels, photos and occasional excursions, a drive now and again, newspapers, cafés, &c., but mean that you must know something of the language, and in the longer tours you must make some stays of three weeks to a month in smaller places, where you can live for 5s. a day. Of course, you will be told of record cheap tours; but remember this, you go to work, and work on bad food in badly-drained hotels may mean fever, which is decidedly not economical. I have read accounts of tours where, from the remarks made as to weather, people, &c., I have been certain that the writer was suffering from over-cheap travelling. Again, it is a mistake to sacrifice your pleasure to unreasonable economy—I mean by omitting an occasional excursion or other semi-amusement on the score of expenditure, because you will find in your subsequent recollection such outings form the most pleasant features of the trip. But if you do make such excursions, see that you have the means to do the thing properly. One sometimes sees people abroad do such things in a shabby way that they should be ashamed of.

Start your tour with extreme care in your accounts and expenses, as, until you have gained experience, you will waste a great deal of money, and will thus load your average unduly, and it will take much economy to counterbalance it. A good plan is to make up your accounts on leaving a place, including the ticket to the next place and the hotel bill, tips, &c., just paid. Reckon up your balance in the train, and note the amount and hour; then, by deducting from the similar statement on the last departure, you can reckon the number of days and the amount spent, which will give you your average. Mr. Anstey, in *Punch*, under the title of "Travelling Companions," has given a good guide to this subject to those who can see the moral. I have only to add that, in my opinion, Scott's advice, never to go with laymen if you want to work, is sound, for, as he says, when they have finished a place you want to begin. I think, too, that some similarity of age is advisable as well as previous acquaintance, because we all go through certain stages of beliefs, and you will, in the abundance of your time for

talking, infallibly discuss, not so much what you are seeing as general theories of art, and to have to refute your cast-off enthusiasms in the person of a younger companion may be salutary, but is somewhat wearing. Bear in mind what the Master of Ballantrae said to Captain Bourke when setting out on their memorable journey, "Either let us agree to bear all things at each other's hands, or else let us part at once." As to travelling alone, no doubt it procures unanimity, but I question if it is not better to bear all things rather than to be out of accord with nature, which disbelieves that it is good for man to be alone. The great advantage is, from an art point of view, that concentration of mind is essential to the receipt of impressions when sight-seeing, and in working you have the advantage of being free to undertake things that require time, knowing that you can go or stay as you please. France, from the generally genial character of the people, and Italy, on account of the greater number of tourists to be met with, are the best countries to travel alone in, but do not do so in Spain, on account of the long, uninteresting journeys that have to be made from town to town, and the not very sociable character of the people, for a really good knowledge of Spanish is required by those who would mix with them. Travelling with another is a drawback to learning the language without question, and to some extent it prevents your seeing so much of the country and people, but, on the other hand, if you have a friend to go with, excursions on foot or otherwise, which you would not make by yourself, are more feasible, and this especially is the case in those which are made for the sake of the scenery, when absence of work to do might make the solitude too much felt.

It is hazardous to rely on finding some one abroad, as you will generally find the parties already made up, and fellow-students are not often met with in certain of the larger centres. It is an interesting chance if you should be able to travel with a foreigner, especially of your own age, and leads to a rapid progress in French, which is probably what he will speak.

Concierges and sacristans should not be ignored, and according to the country should be their treatment. In France they are very powerful and often troublesome; in Italy and Spain, remember that attempts to postpone your visit to their customary "to-morrow" may be met by saying that you are leaving to-morrow or to-day, as the case may be, when the loss of the prospective tip may be found to be effectual in removing difficulties. It is a good plan not to alarm a sacristan or concierge by going with a big board and apparatus, as if you were going to be a long time at work, but rather to begin quietly at first until they have got used to you. The thing is simple enough—no one average man wants to do more work than he need or to be put to much trouble, and the aim of the average sacristan is to put through as many visitors and to receive as many tips as possible during his working hours, and hence popular show-places are the worst to work in, the artist, and especially the architect, being a troublesome intruder. You will do well to ascertain the hours of the attendants and to conform to them as much as possible, and when going round in a party in the regular official circuit of a show-building, you should, I think, in politeness keep with the party, and on its completion ask for permission to make further study. In this way you may obtain as a favour what would only be obtained by force with much loss of time and temper.

Introductions to architects and others abroad are very pretty things, and sometimes interesting information is obtained from the people called upon, but, firstly, you may have no end of trouble in finding the addresses in a strange place; secondly, in calling the best hours of the day will have to be employed, and, thirdly, the interviews themselves may take up a disproportionate amount of time. They should not be used by those who are not at home in the language of the country, and it is no easy matter to converse on all the subjects that will be raised.

The Royal Institute of British Architects' travelling card, the Academy bone, and, lastly, the Architectural Association membership ticket, will be found of service as credentials when applying for leave to draw and as proof of your profession. The Royal Institute of British Architects' card, however, is not well got up; it compares most unfavourably for impressiveness with the 3s. 6d. Government passport which anyone can get. Moreover, the face should be in the language of the country, and not the back, as suspicion is caused by the request to read the back, and the presence of other languages there also is not favourably regarded. An adapted copy of the Government passport, and one for each country, would be the best thing to give students. The letter given to prize students is, however, favourably received, though it is only in English; it is big, and looks official. With it you are taken for a student sent by the Government, for the English private enterprise is not understood in countries where the State does most things.

At the conclusion of the paper a hearty vote of thanks was accorded to Mr. Bolton, as proposed by Mr. R. Phené Spiers and seconded by Mr. Banister F. Fletcher.

(To be concluded.)

"Antiquity after a time has the grace of novelty."—HAZLITT.

RICKMAN'S LETTERS ON THE ARCHITECTURE OF FRANCE AND ENGLAND.

(Continued from page 342.)

LETTER V.

I NOW resume my consideration of the architecture of England and part of France, and I intend in the present paper to notice such buildings in both countries as are either known to be of a date prior to the year 1000, or in their clear difference from anything of later date, may, from that clear difference, and their relation to works known to be before the year 1000, be well permitted to be considered of an earlier date, until proved to be of a later one.

In France there are the following buildings:—The walls of the city of Bayeux; the theatre at Lillebonne; the church of St. Germain, at Rouen; the ancient portion of a church at Beauvais, now called the Basse Euvre. All these present clear and definable Roman features.

At the theatre at Lillebonne we have regular ashlar masonry with rubble backing; the front work very well done, with good clean joints. Also a wall with small stones about 6 inches long and about 4 inches high in the courses; these form a thin skin, and have rubble backing, but with horizontal courses of what are called Roman bricks, *i.e.* flat tiles about 14 inches long, 11 inches broad, and not quite 2 inches thick. These tiles act as binding courses to the small stone and rubble of which much Roman walling is constructed.

This horizontal bond of tiles accompanies nearly all the Roman walling which is built of small stones, both in England and that part of France included in my present observations.

It is present in the walls of Bayeux, where the courses of stone are irregular—some small, some large; in the church of St. Germain, where the walling is of squared stone, rather larger than the small stones at Lillebonne; and here there is also an outer tier of bricks around the arches, like a drip-stone. It is also in the Basse Euvre, at Beauvais; here the walling is small stones with large joints, and the exterior arches, as well as the drip course round them, are partly formed of Roman bricks. The interior walling of this building is the white stone of that country, which, though so soft as to be easily worked, retains its edge and its form completely to the present time. This building (now a firewood warehouse), though sadly neglected, has much of its interior work, plain round arches and square piers, in very good condition.

These buildings are in France so well known to antiquaries, and their dates so constantly acknowledged as prior to the year 1000, that I trust I may be excused the task of attempting to prove that they are of that date, and thus save the valuable time of the Society.

In England we have, first, a variety of Roman walling acknowledged to be such.

These walls are in various counties, from Northumberland to Kent, and many of them (and I believe all in which the construction was necessary) have the bonding bricks more or less frequent.

There are a few Roman examples in which, from the mode of construction with large blocks of stone, it does not appear that the bonding bricks were used. Of these examples I may mention two which remain in a more perfect state than, considering their age, could well have been expected.

The first is the North Gate at Lincoln, which, as when first erected, is still used as the passage through the walls. This gate had originally an impost and architrave moulding; but they are now hardly visible.

The second is a portion of the Roman Wall near the military road from Newcastle to Carlisle; its walling is well done and in a very perfect state, and near it is a quarry of most excellent building stone, from whence that used in the wall appears to have been taken.

I do not intend to notice all the Roman works known to exist in England, but merely a few for the purpose of showing the similarity of construction with those noticed in France; and of referring to them as linking with those churches which I suppose to have been erected in England before the year 1000.

What is called the Jews' Wall, at Leicester, is built with many of the flat tiles, or Roman bricks; and the portions of Roman wall still remaining near St. Albans, in Hertfordshire, and at Richborough Castle, in Kent, have these Roman bricks used as horizontal bond, in the same way as we have noticed in the French edifices.

I shall now, previous to enumerating the buildings which I have reason to believe were erected before the year 1000, state those particularities of their masonry, their forms and their details, which, by the difference from works of known Norman date, give reason to suppose them of this very early period.

First, as to the masonry, there is a peculiar sort of quoining, which is used without plaster as well as with, consisting of a long stone set at the corner and a short one laying on it, and bonding one way or both into the wall; when plaster is used these quoins are raised to allow for the thickness of the plaster. Another peculiarity is the use occasionally of very large and heavy blocks of stone in particular parts of the work, while the rest is mostly of small stones; the use of what is called Roman bricks, and occasionally of an arch with straight sides to the upper part instead of curves. The want of buttresses may be here noticed as being general in these edifices, an occasional use of portions with mouldings much like Roman, and the use in windows of a sort of rude baluster. The occasional use of a rude round staircase, west of the tower, for the purpose of access to the upper floors; and at times the use of rude carvings, much more rude than the generality of Norman work, and carvings which are clear imitations of Roman work.

All these marks do not in every case appear in each of the edifices; but they are all more or less united to one another, and thus form a very interesting series. The buildings of this character as yet found are:—

1. The church at Whittingham, in Northumberland.
2. The west end of the church of Kirkdale, Yorkshire.
3. The church of Laughton en le Morthen, Yorkshire.
4. The tower of St. Peter at Barton-on-the-Humber, Lincolnshire.
5. Part of the west end of Ropsley Church, Lincolnshire.
6. The east end of the church of Repton, Derbyshire.
7. The tower of the church of Barnack, Northamptonshire.
8. The east end of Whittering Church, Northamptonshire.
9. The church of Brigstock, Northamptonshire.
10. The church of Brixworth, Northamptonshire.
11. The tower of the church of Earl's Barton, Northamptonshire.
12. The tower of Clapham Church, Bedfordshire.
13. The tower of the church of St. Benet, Cambridge.
14. The tower of the church of St. Michael, Oxford.
15. A part of the tower of Trinity Church, Colchester.
16. Some small portions of the church of Stoke d'Abernion, Surrey.
17. The east end of the church of North Burcombe, Wiltshire.
18. The doors (now stopped) of Britford Church, Wiltshire.
19. A small part of the church of Worth, Sussex.
20. The tower of the church of Sompting, Sussex.

This list comprises twenty edifices in thirteen counties, and extending from Whittingham, in Northumberland, north, to Sompting on the coast of Sussex, south; and from Barton-on-the-Humber, on the coast of Lincolnshire, east, to North Burcombe on the west. This number of churches extending over so large a space of country, and bearing a clear relation of style to each other, forms a class much too important and extensive to be referred to any anomaly or accidental deviation, for the four extreme points all agree in the peculiar feature of long and short stones at the corners, and those stones of a varied character, and all easily accessible in their respective situations.

These English examples of towers and churches I may, I trust, be permitted to describe with some minuteness, so that persons who visit them may know wherein consists their likeness to each other, and difference from other styles.

From what I have seen I am inclined to believe that there are many more churches which contain remains of this character, but they are very difficult to be certain about, and also likely to be confounded with common quoins and common dressings, in counties where stone is not abundant, but where flint, rag and rough rubble plastered over form the great extent of walling.

In various churches it has happened that a very plain arch between nave and chancel has been left as the only Norman feature, while both nave and chancel have been rebuilt at different times, but each leaving the chancel arch standing. I am disposed to think that some of these plain chancel arches will, on minute examination, turn out to be of this Saxon style. I am the more induced to think so from the tower at Whittingham, in Northumberland, having close to it one such plain arch, and next to it another semicircular arch, which would be called, if not early, certainly not very late Norman, yet strikingly different.

As the portion of France I visited, though containing a great variety of large edifices, was not visited as to the small churches to an equal extent, owing to the difficulty of getting to places not on the high roads, I cannot say whether there is anything like our combination of long and short stones; only one church I saw at a village near Beauvais had any such antiquity, by tradition, as before the year 1000, and there the

only feature noticeable was a resemblance to the walling of the Basse Œuvre at Beauvais, both being formed of small stones with large joints.

I shall now proceed to state more clearly the distinctions of this early or Saxon style, and then to describe those edifices above enumerated.

Arches.—Where of considerable size they are semicircular, but there are smaller apertures of doors and windows with straight slopes to the aperture. In some doors, and in some larger arches, there is a regular impost at the spring, which has a rude resemblance to Roman mouldings.

In the small windows a sort of rude baluster, such as might be supposed to be copied by a very rough workman by remembrance of a Roman baluster.

Masonry.—First, a sort of quoins or framing of stone projecting from the face of the wall, the filling-in often of small rough stonework, and sometimes plastered. Second, the use of very large pieces of stone, much larger than usual in Norman, for parts, while the remainder is of small and very roughly-hewn stone.

Staircases.—In two instances (more perhaps may hereafter be found) there are on the west side of the towers circular staircases, equally rude as the masonry of the church; but in one of these instances this staircase has been found to be an addition.

Bricks.—It is not easy to discover whether the Roman bricks (or, rather, flat tiles, as we should now term them) that we find in one at least of these edifices have been laid before and are the ruins of a former building, or were made for the purpose and used new.

Ornaments.—In one, if not more, of these buildings there are some very rude carvings, more rude than most Norman work.

Plan.—All the corners square, and there seems no instance of a buttress to these buildings which is not evidently an addition.

As I cannot presume to settle which of these buildings is of the earliest date, it will, I think, be better to take them nearly geographically, and commencing at the most northerly.

1. WHITTINGHAM CHURCH, NORTHUMBERLAND.

This church has a tower and the west end of the aisles and one arch on the north side, all appearing of the same early style. There are Norman portions, but they are clearly of a different and later date, and parts of the church are even later still with some modern mutilations.

The corners of the tower and exterior angles of the walls of the aisles are clearly of long and short stones of a very strong coarse gritstone, and the whole walling being of the same stone as the quoins, and no plaster required, the construction of the masonry is very conspicuous. The battlements and a part of the upper storey of the tower appear to have been altered; but the upper aperture has a rude baluster between the two windows, thus presenting two features, generally the most striking and constant in these early buildings. One arch of what appears to me to be the original nave remains; it is very plain, has a large rude abacus or impost and a plain square pier; it is now stopped and forms part of the vestry. The next arch eastward on the same side is a common Norman one, with the usual round pier and a capital, with a sort of bell and a square abacus. The remainder of the church is later, and of little comparative interest. The apertures in the tower have been much mutilated, yet those above have the baluster sufficiently clear to mark the style.

This church is situated about 300 yards out of the great road, and presents nothing attractive to the eye at a distance, nor do I believe it has ever been described.

2. THE CHURCH OF KIRKDALE, YORKSHIRE.

This church is also out of the road, between Helmsley and Kirby Moorside, in a valley near the celebrated Bone Caves. It is a small edifice, mostly of much later date. It has a stone on the south side with a Saxon inscription, but as this has been removed from its original place, it is now no evidence of itself as to what part of the church is Saxon; but as the western door, now stopped, and the arch to the chancel are both of them very rude, though in some degree resembling Norman, they may, I think, on a careful examination of them be considered portions of the old building.

3. THE CHURCH OF LAUGHTON EN LE MORTHEN,

between Sheffield and Worksop, is in Yorkshire, away from any public road; it is a fine church with a lofty spire visible at a great distance. The Saxon portion of the church consists only of a door on the north side, close to the western wall; it is evidently part of a more ancient structure, carefully preserved and surrounded with more modern masonry of very different stone, and is as clearly a long and short construction as Whit-

tingham or Barton. The church, for a country place, is a large one, and has a nave, aisles and large chancel. A portion is Norman, and this, as well as some more modern parts, is built

CHURCH OF LAUGHTON EN LE MORTHEN, YORKSHIRE.
Door in the Western Division of North Aisle.

of what appears to be a magnesian limestone, yellow at first, but growing a fine grey; the ancient door is, however, of a very different stone, being a dark red sandstone of a strong grit, whence obtained I do not know; but in the Norman chancel, intermixed with the grey stone, are several portions of the red sandstone built irregularly, as if portions of an older building, and on the inside are two niches—one evidently a seat with a plain sink and a semicircular head, and another, which seems to be a cupboard, with a straight arch top, but both of these are plastered and whitewashed, so that I could not examine of what stone they were constructed.

The later portions of this church are curious, for the Norman piers on one side of the nave are capped by a sort of upper square capital of Perpendicular work, which I have not seen elsewhere, and which is intended to raise those piers to the height of the piers on the other side of the nave, and from each spring arches of the same character corresponding with the later piers.

4. THE CHURCH OF ST. PETER AT BARTON-ON-THE-HUMBER, LINCOLNSHIRE.

This always goes by the name of the old church, and the other church, within a very short distance and called St. Mary's, the new church. Now no part of the new church is much later than A.D. 1300, and except the tower no part of the old church is so old as the year 1300; thus referring to the tower as the ancient part of the old church, and as the piers and arches of the nave of the new church are Norman, though rather late, it makes the old church of course as old as Norman, and from the circumstance of the belfry storey above the ancient tower being Norman—and certainly not late Norman—it gives a sort of *prima facie* evidence of a greater antiquity to the tower, and this evidence, and the complete difference from Norman in this tower, first attracted my attention and led me to look for similar ones in other parts of the kingdom.

This tower has the long and short quoin and rib stones, with the baluster window for what appears to be the original belfry storey before the addition of the Norman belfry. These rib and quoin stones project, are filled in with rough rubble walling and plastered. There is one door with a round arch, and one straight. The walls of the tower are thick, and there is no appearance of any staircase having ever existed. The church is mostly of a Decorated character. I consider this tower the most pure specimen of the long and short work, and particularly deserving of a visit from those who wish to see this style fully exemplified, and the Norman belfry is valuable from at once limiting the date of the tower to an early period.

5. ROPSLEY, LINCOLNSHIRE.

The long and short remains in this church are confined to a portion of the west end near the tower, and here also it is mixed with Norman work; a Norman north aisle appears to have been added.

6. THE EAST END OF THE CHURCH OF REPTON, IN DERBYSHIRE.

Here the long and short appearances are very small, only two ribs by the side of the chancel window, which is an insertion, but there is a crypt which is more like Roman work in some parts than Norman, and here are early Norman portions in the church, and all these portions are so blended with later work that it is very difficult to say where one ends and the other begins, but I have no doubt that some part of this church is of Saxon date.

7. THE TOWER OF THE CHURCH AT BARNACK, IN NORTHAMPTONSHIRE.

This tower has quoins and rib-stones like Barton-on-the-Humber, but the stones are more carefully squared and laid, and there are certain ornamental portions built into the walls, which give it a very different air to that of Barton, but it had no staircase, and to supply this want the lower storey was groined, and in one corner a circular staircase of early English date carried up within the square of the old tower. The arch into the church is curious from its singularly rude imitations of Roman mouldings in the impost and architrave. On the tower is a later belfry and a short spire.

This church is near Stamford, but not on any high road; it is a handsome structure, and deserving of attention, exclusive of the more ancient portion. It is built of Barnack stone, which seems to have been very extensively employed at one time, though the quarries are not, I believe, now worked. It is an oolite, in which are embedded numerous small shells, from whence it weathers very rough and open.

(To be concluded.)

THE MONASTERY OF ST. MARY DE PRÉS.*

THERE is nothing now but a slight unevenness of the ground, a little way down on the right-hand side of the Gorhambury drive, to indicate the site of the Benedictine nunnery of the Blessed Mary of Prés or the Blessed Mary in the Meadows, but it is surprising, considering the smallness of the monastery, to find so much documentary evidence as we do concerning it. From this I propose to sketch briefly the history of the monastery, and to attempt to show how the nuns lived and what they did. It is to be hoped that at some future time excavations may be made at the site and a ground plan of the buildings obtained, as there is so little at present known concerning the arrangement of these small English nunneries.

The story of the foundation of Prés, told by Matthew Paris, is as follows. A poor man of the town of St. Albans in 1178 had a dream in which St. Alban appeared to him and revealed the place of sepulchre of St. Amphibalus. Upon examining the spot indicated, the relics of the saint were found between two of his companions. As the relics were being brought from Redbourn to St. Albans, the monks of the abbey went out in procession to meet them with the shrine of St. Alban, and when the shrine of St. Alban approached the relics of St. Amphibalus it became so light that it could be carried by two brothers, "yea, even by one without difficulty," when at other times it was so heavy it could be scarcely moved, so strongly was the holy martyr attracted to his teacher and master. Some ten or twelve years afterwards a certain faithful man of Walden, we are told, while calmly reposing in deep slumber had a vision, in which there appeared to him a venerable cleric, bright as a ray of sunlight, who, upon being asked, stated that he was St. Amphibalus, the master and converter of Blessed Alban, protomartyr of the English, in whom he was well pleased and in whose glory he was gloried, and after referring to the attraction the place where his relics rested had had to the shrine of St. Alban, the visionary saint added, "Go, therefore, to Abbot Warin and tell him for me that the same place should be honoured with fitting reverence."

Upon the saint's messenger coming to the abbot and relating his vision, the abbot determined to honour the place by building there a church. And being apparently a man of impulse and energy, he within a very short space of time completed the buildings, endowed the monastery, put in the religious persons and instructed them in religion, lest any one should say of him that he commenced to build but was unable to complete his work. He dedicated the church to the Blessed Mary, and made John de Walden, son of the messenger of St. Amphibalus, the first master and proctor, who, although a layman, by preaching to the more simple he instructed many, and calling upon them to follow virtue, he refrained himself from vice. Abbot Warin having completed the buildings, put into them leprous nuns and restricted them within certain bounds, lest they should be entangled in the errors of the world, and kept

* A paper by Mr. William Page, F.S.A., read at a meeting of the St. Albans Architectural and Archaeological Society, and published in the *Herts Advertiser* and *St. Albans Times*.

them removed from the leprous men at St. Julians. It would appear from the wording of the Gesta that there had been both men and women at St. Julians.

By a charter dated September 15, 1194, the abbot granted to the monastery of Prés the place in which the church was built, together with the monastic buildings on both sides of Watling Street, certain procurations, the first and last loaf at every baking, license to grind corn at certain mills, thirteen old garments of the monks a year, and certain alms, corrodies, &c. He also provided that their chaplain should have daily from St. Albans Monastery a loaf of a monk and two measures of ale of the monks, and two dishes from the kitchen of the guest-house, and their clerk a loaf of an esquire and one measure of ale of a knight, and one dish from the kitchen of the guest-house; also that the same chaplain and clerk should yearly receive a mark from the church of Walden, and half a mark from the church of Newham. He also endowed the house with the tithe from the Lordship of Luton, and the tithe from the rent of the Stone House upon the wall of the cemetery of St. Albans, certain rents in Cambridge, pannage for pigs and provender for horses, a certain woodland called Coppedethorn, with firewood and some other tithes. The charter ends with the abbatial curse. If any one should presume to take anything from the abbot's gifts, let his name be erased from the book of life, and let him participate in the perpetual punishments with Judas the betrayer. Amen. As all the possessions granted belonged to the abbey of St. Albans, Abbot Warin was much blamed for impoverishing the abbey in order to found Prés.

King John, who is not usually accredited with very much liberality, was the greatest royal benefactor to St. Mary de Prés. On June 14, 1199, he granted to the church there the right to hold a fair yearly on the vigil and feast of the nativity of the Blessed Mary the Virgin, which fair was held yearly at Romelands, in St. Albans. Also on May 1, 1204, he gave the same church some sixty acres of land about St. Albans, and again on May 18, 1215, he granted a protection to the inmates of the house.

The next mention I have found in chronological order concerning the house of Prés is the consecration of the cemetery there, which service was performed by the Bishop of Down during the abbacy of William de Trumpington (1214-35). Under Abbot Warin's charter, Richard, the keeper of the house of Prés, on the death of Abbot Trumpington in 1235, claimed a corrody or a supply of meat and drink for one person, as had been supplied upon the deaths of former abbots, which was granted to him. About this time the house of Prés appears to have become very poor and the buildings dilapidated, so that in the account given in the Gesta of the visitation of the Bishop of Norwich, by order of the Pope and Henry III. for the taxation of the tithe to be granted for the Crusade, it is described as the church of St. Mary de Pratis, where the poor women scarcely have the necessities of life. Possibly at the intercession of this bishop, Pope Alexander IV. came to the assistance of the house and issued a bull in 1255, granting forty days' indulgence to such persons as should contribute towards the repair of the buildings, and again in the two following years similar bulls were issued.

I have seen no record relating to the house of Prés for nearly a hundred years after this date, and as about the middle of the fourteenth century there commences a series of the accounts of the priory made up yearly and preserved at the Public Record Office, which illustrate the life within its walls, it may be well to digress here from the chronological order of events, and consider how the inmates of Prés lived. First with regard to the buildings, as there are now no indications of the positions of any of these, I cannot lay before you a ground plan, but, speaking generally, the plans of most nunneries were similar, adapting themselves, of course, to local requirements. There was the cloister, around which the various buildings ranged. The church was usually to the north, running, of course, east and west; the chapter-house on the east side, with probably a parlour or hall adjoining, and over these was the dormer or sleeping apartments; on the south was usually the frater or dining-hall, and on the west were the guest chambers, kitchens, &c. Mr. William Brown, in a paper upon some small Yorkshire nunneries, which he contributed to the *Yorkshire Archaeological Journal* (vol. ix.), states that most of the chambers were comfortless abodes, plastered inside and weather-boarded out; few of them had fireplaces, and in some cases the windows were unglazed and were placed with an utter disregard of what was under or above them. The cloister-walk or ambulatory was sometimes glazed in the Yorkshire priories. With reference to Prés, I have found mention in the accounts before referred to of the church with the chancel of the nuns and sisters, the cloisters, the chapter-house with the great solar over it, the chamber of the nuns, the house of the sisters, the aumbry, the great hall, the red hall, the dormitory, the chamber of the guest-house, the frater, the hall of the prioress, the wardrobe, the rere dormer, the kitchen, the laundry-house, the stable, the dove-house, the cemetery of the nuns and sisters, the garden, &c.

The buildings had apparently all of them tiled roofs, and the windows were all glazed. There appear also to have been fire-places in the dormitories, as there are items for coals to be expended there. The monastery was possessed of a clock, the cost of the repair of which occurs in the account for 1461.

Concerning the inmates of the buildings we obtain some little information from these rolls of accounts. At first the house was ruled by a master, and was merely a hospital for leprous women, but as leprosy died out in this country it became purely a monastic establishment. The masters or wardens continued to manage the affairs of the priory till the middle or end of the fourteenth century, and afterwards, to the dissolution of the house, the direction of all the affairs devolved upon a prioress as in an ordinary nunnery. I find, however, in the bulls of Pope Alexander IV. on behalf of the priory as early as 1255, and in the early accounts, mention of the Prioress of Prés, at the same time as the house was under the rule of a master. At the time of the foundation of the hospital the inmates consisted apparently of only leprous sisters, with probably a professed superior to take charge of them. Shortly afterwards, however, there were two classes, namely, nuns and sisters, and these continued down to the abbacy of Thomas de la Mare, of St. Albans, whose sister Dionisia, as she is called in the Gesta, or Alice in the accounts of Prés, became a professed nun of this house in 1342, when she paid 2*l.* at her entry. This lady from the position of her brother probably became prioress, and shortly after he was elected Abbot of St. Albans, Thomas de la Mare altered the constitution of the house, doing away with the remains of its character as a hospital and making it purely a nunnery. He ordained that the sisters, the successors of the leprous women, should become nuns, and from thenceforth no more sisters should be received. And whereas the greater part of the nuns had been illiterate and so unable to say the services, he ordained that the then present and future nuns should learn to read, that they might say the services at the canonical hours, and for this he gave them six or seven ordinals from the Monastery of St. Albans. He further commanded that from thenceforth all the nuns should profess the rule of St. Benedict in writing, in the presence of the Archdeacon of St. Albans or a monk to be appointed by the abbot. It is about this time—viz. in 1357—that there is the last mention I can find of the master or warden of the house, and the prioress takes his place in all deeds and charters, and in the control of the monastery and all its possessions, and this was the date I fancy at which the house was changed from a hospital to a nunnery.

DISCOVERIES IN EGYPT.

EVERY season, says the *Times*, brings more spoil of the Egyptians, and it is always the unexpected that we must expect. A private tomb gave up the kings of Thebes; the vaults of a priestess of Hathor were found filled with mummies of priests of Amen. Priceless scraps of literature have been recovered from cheap *papier-mâché* coffins, and farm-accounts have been known to bear a lost poet on their reverse. The latest surprise is that in a Memphite tomb, rifled ages ago, hard by a pyramid, supposed to be of the sixth dynasty, has been discovered a royal treasure of the twelfth.

The pyramids of Dahshur rise on the left as one rides to the Memphite necropolis at Sakkara, the nearer one being a formless mass of brickwork, almost cut in half by treasure-seekers, and buried deep in drift. No royal chamber has ever been found in it, and M. de Morgan, the present director-general of the Service of Antiquities, conceived the idea that it might be only an enormous *mastaba*, built above the royal tomb. He began, therefore, in February last to dig about its roots in the hope of hitting the mouth of the shaft by which the burial must have been introduced from outside. The desert all round the pyramid base was found full of tombs, square-bricked shafts descending from ruined *mastabas* to the grave-chambers. All had been rifled, and nothing of interest resulted at first but sculptured slabs and *stèle* from the *mastabas* and Canopic jars and chests. From the foot of one shaft, 30 feet deep, a winding passage, roughly hacked, was found leading into the bowels of the rock. Groping on, the explorers debouched into a vault, nearly filled by a fine sarcophagus inscribed with the name of Nefert-Heut, a queen. Alas! it was broken and empty, rifled by the same hands that had cut the passage. A door, however, led into another gallery, in this case no thieves' work, but an original part of the tomb. It was straight for a long distance, chambers opening on the left, each with rifled sarcophagi and Canopic chests. The furthest group of vaults yielded the name of a princess, Seut-seubetes, but was apparently as empty as all the rest. M. de Morgan, like Schliemann, is not content till he has reached rock, and therefore set his men to pick over the floors, expecting no reward beyond the credit of clearing a fine tomb, structurally interesting, though completely void. In the floor of a passage in the group of chambers belonging to the princess the picks encountered a patch of soft earth. A few

inches lower the remains of a silver-encrusted box were disclosed, and piece by piece below its crumbling lid was found the first instalment of the treasure of Dahshur. A long necklace of amethyst beads, a second of amethyst, turquoise, carnelian, *lapis lazuli* and gold, a kohl-pencil in exquisite gold-bead work, a bunch of gold rose-petals, three finely-cut *scarabæi*, the gold face of one bearing the royal name of Usertasen III., couchant lions and other tiny pieces in gold; these were all admirable, but eclipsed by two objects in mosaic-work, namely, a pendant or brooch shaped like a lotus and set with *lapis* and carnelian, and a royal pectoral, on which two crowned hawks support the cartouche of Usertasen II. The plumage is in stripes of *lapis* and turquoise, the symbols of the royal name in these and carnelian; the whole is set in gold and worked on the reverse to represent the same scene as the front. Whether for purity of design, exquisite colouring or absolute finish it equals any piece of jewellery in existence. It would be a *chef-d'œuvre* of the goldsmith's art of to-day; made 4,500 years ago it is a miracle.

A few yards further along the passage was found a second box hidden like the first. Two large pectorals were in it. On the first, two figures of Amenemhat III. smite the Asiatics; the design is crowded and less pleasing than the pectoral of Usertasen II., though the mosaic of stones and gold is not less finely fashioned. On the third pectoral two hawk-headed apes beneath the cartouche of Usertasen III. trample on prostrate men. Nothing for sheer finish excels this piece in the whole treasure. For the rest, we can only give a catalogue of the most beautiful contents of the box. There were large cowrie-shells of gold, pestle and mortar in gold and *lapis*, rings with beautifully graven *chatons*, necklaces of amethyst and carnelian, large rose-petals—one with a wonderful mosaic centre—mirrors with gold handles, gold lion masks, and a second kohl-pencil adorned with a pattern of gold beads, soldered on one by one, a marvel of delicate work. There is not a single object in the treasure not remarkable; the whole can be fitly compared only to Schliemann's find in the circle graves at Mycenæ.

Why were these treasure-coffers so hidden, and who hid them? Perhaps the legitimate owners, fearing spoliation; perhaps robbers waiting for a favourable moment to carry them away. So cunningly concealed were they that the chief wonder is how they were ever found at all; and M. de Morgan's discovery of them will assuredly rank among the most remarkable successes in the records of explorations. He is digging still for the royal chamber, but up to the present moment the pyramid has preserved its secret inviolate.*

The most considerable excavation carried out during the past season in Egypt has been that of the Exploration Fund in the temple of Queen Hatasue at Deir el Bahari, near Thebes. If M. de Morgan has revealed a treasure, M. Naville is bringing to light a temple. The unique pile of buildings which the Queen erected and adorned to serve as funerary shrine for her father, her husbands and herself, has been almost entirely buried for ages between earth-slips and the *débris* of a Coptic convent. Thirty years ago Mariette laid bare a small portion, and enriched the world with the famous wall pictures of the Queen's naval expedition to the land of Punt, but the rest was left under mountains of rubbish till last season. Thanks to the Egypt Exploration Fund, the whole of this beautiful monument of the greatest period of the empire is now in process of being exhumed and restored. It is built on three terraces; the upper was cleared almost entirely last season, and among other things a unique high altar was laid bare, and a side of a magnificent ebony shrine of Thothmes II. discovered. The latter is now mounted between glass at Ghizeh, and is the finest piece of ancient woodwork in the collection.

Both this season and the last many hundreds of blocks have been recovered, sculptured with the Queen's exploits, her wars and the transportation of her obelisks from Syene. So long buried, the colouring of these scenes is as vivid as their execution is admirable, and they will bear comparison with any work of the eighteenth and nineteenth dynasties, even that of Seti I. Abydos. During the past winter the middle terrace also has been cleared in great part. A fine colonnade, a hypostyle hall with brilliant paintings, and a portico adorned with scenes relating to the Queen's birth have been opened once more to the light of day. The portico reliefs have a peculiar interest as being apparently originals of the famous scenes in the temple of Amenhotep III. at Luxor, in which his relation to an immortal father is portrayed. In clearing so large a space many small things must always be found, and in this instance there has been a large find of ostraka, hieratic, demotic and Coptic, of blue scarabs and amulets of the famous local ware. The work is to be resumed next season, and when all is done the Egypt Exploration Fund

will have the credit of having restored to the world one of the most singular and beautiful monuments of antiquity.

Thirty miles lower down the river Mr. Flinders Petrie has met with his usual success at Kuft, the site of ancient Coptos. His marvellous instinct of discovery led him to select the temple site which lies in the midst of the Roman city, and, turning over the *débris* from end to end, he has found most interesting remains of the worship of Khem in all periods. In the foundation-sand of the Ptolemaic restoration he lighted on three *colossi* of the god, so strange and rude in style that he supposes them to be almost prehistoric, the work of the first immigrants from Arabia before Mena founded the first dynasty. Carved on them in low relief are symbols, shells and animals, whose style may help to fix their period. A lively discussion is likely to arise, and we may expect to hear them referred to every date from that of the Arabian immigration to the occupation of Coptos by the Blemmyes after our era. Other finds of Mr. Petrie's, however, go back far enough. A fragment of alabaster bore the cartouche of Khufu of the fourth dynasty, and slabs of a pavement of Thothmes III. showed on their reverse sides scenes from the temple of the eleventh dynasty, unfortunately very imperfect, for they are the earliest temple sculptures known. A door-jamb was carved with the finest work of Usertasen I. of the twelfth dynasty. Foundation deposits of the eighteenth, a triad and *stela* of the Rameside period, pottery of all the dynasties from before the pyramid builders to the Roman, make up with many odds and ends a find equal in interest to any that Mr. Petrie has ever made, except perhaps at Naucratis. We may mention also that a remarkable Roman inscription was found at Kuft shortly before Mr. Petrie's arrival, giving a list of tolls to be paid at the Red Sea gate of Coptos.

A very important symptom of the past season has been the awakening of interest in ancient Alexandria, and we shall probably hear a great deal about the Ptolemaic and Roman capital in the future. It is the unexplored site in Egypt, and it is really astounding that we should know so little of what was once the first city (and has always been among the first) on the Mediterranean. The meeting-place of so many races, bound up with Jewish and early Christian history, an unrivalled centre of culture, the burial-place of the greatest of ancient conquerors and of a long line of his successors, the most singular and favoured city in the Roman empire, Alexandria has limitless possibilities. The ancient city lies deep under the modern, but now that the Municipality is favourable, the new museum has been organised, and persons of local influence are at work, we may hope that an exploration has been begun which will prove of extraordinary interest, if carried through.

Odds and ends of work there have been many. The beautiful temple of Kom Ombo has been rescued by M. de Morgan from the wash of the Nile, and, albeit a little too thoroughly swept and garnished, presents a very fine appearance. Members of the French mission have copied its inscriptions throughout, and the plates will appear shortly in the publication of "Unedited Monuments," promoted by the director-general. Mr. Sayce has been exploring Nubia, and finding forts and graffiti and *stela*, whereof he has given account in the pages of the *Academy*. Dr. Hess has been searching the same shores for demotic texts, but the result of his labours is not known. Captain Lyons, R.E., has brought back much information and some antiquities of note from the Oases, and Mr. Bloundell is about to explore the Temple of Ammon at Siwah in the course of a wild and difficult journey which he hopes to terminate in the Cyrenaica. Messrs. Tyler and Somers Clarke are continuing their work at El Kab.

EGYPTIAN DECORATIVE ART.

A COURSE of lectures on "Egyptian Decorative Art" has been commenced by Dr. W. Flinders Petrie at the Royal Institution, London. He said that bounds must be set to a study which might be made to embrace almost every example of ancient work known to us in the land. The Egyptian treatment of every object was decorative, and these lectures must be limited to the historical development of the various motives or elements of decoration, notwithstanding the temptation to examine the historical connection of Egyptian design with that of other countries. The love of form and drawing was perhaps a greater force with the Egyptians than with any other ancient people. The Babylonians and Chinese had, like them, a pictorial writing; but while these dropped that for easier abbreviation, the Egyptians never lost sight of the original picture, and although the current hand altered much, for 4,000 or 5,000 years the true hieroglyphic representations were maintained. These were also decorations; their position was ruled by their effect as a frieze, like the beautiful tile borders of Cufic inscriptions in Arab architecture, and inscriptions are never cut across figure-sculpture as in the barbarous custom of Assyria, and signs were often transposed in order to group them harmoniously in a graceful scheme. The consequence was the most beautiful writing that ever existed, and the Egyptian

* The total number of pieces in gold found in this tomb was 165, besides 240 beads of amethyst, 70 beads of emerald, *lapis lazuli* and carnelian, and a larger number of smaller beads of various precious stones. The total weight of gold pieces found was 314½ grammes.

became the father of the world's ornament; while in the adaptation of scenes of peace or war to the gigantic wall-surfaces of pylons and temples he has never been surpassed. The question of the origination of patterns at one or more centres has been as much disputed as the origin of man from one or more stocks; but we have less evidence of re-invention than of copying. Weaving and basket-work have influenced the uniformity of patterns in different countries. Mr. Goodyear has brought together much evidence of this descent of design along the well-known historical lines of intercourse. On a less scale this is to be seen in the prehistoric bronzes of Upper Bavaria, in which the designs are partly Italic, partly Mycenaean. We can see a source for most of our familiar elements of design in the decoration used in Egypt long before any example is known out of that land, and therefore we must study Egypt itself. Four divisions may be made of these elements—the simplest geometrical ornament of lines and spirals and curves; the natural ornament of copying feathers, flowers, plants and animals; the structural ornament arising out of architecture; and lastly, symbolic decoration, like the globe and wings, the scarabs, or the various hieroglyphs. As to geometrical decoration, one of the simplest is the zigzag line, so simple that one is astonished to find, as to two of the easiest modifications of it, that the waving lines instead of angular waves are not found till 1500 B.C., and the zigzag with spots in the spaces is as late and generally foreign to Egypt. This use of spots for filling in corners we first see in the garments of Amu or people of Northern Arabia in the twelfth dynasty, up till when no spot is seen except for the centre of a square; but the Amu dresses are covered with spots in every space, and even along the bars and stripes of colour, and it is so also with the Phœnicians or Kelts. This use of dots is a foreign or Asiatic element, akin to the filling in of spaces on early Greek vases with rosettes and other small ornaments. When the zigzag line came to be used on metal-work or pottery, then curves were readily introduced. On a golden bowl repeated waves are shown deepened so as to receive further figures. The spiral or scroll is one of the greatest elements of Egyptian decoration, only second to the lotus in importance, to a development of which some have attributed it, and it has been said to represent the wanderings of the soul. The older group of spirals are the scarabs, the others those continuous patterns on ceilings, furniture, &c. The earliest scarab which can be dated is one of Assa, of the fifth dynasty, on which a bordering line is interrupted at the ends and turned in to fill the space on either side of the name, and this is a frequent case until the twelfth dynasty, in which any continuous spiral design is first to be observed. Those spirals may be described as coils, hooks, links, chains; but when the same line is maintained unbroken it is a continuous spiral of all varieties of coils, hooks or links. The spiral was developed apparently under Usertasen I. into a chain of coils drawn with great beauty and regularity, showing the design to be a novelty, and in no later reign were spirals ever so beautifully and perfectly executed, although the type was revived under Amenhotep II. In the twelfth dynasty it was combined with the lotus in perhaps the most perfect design that remains on any scarab, a continuous coil with flowers and buds in the spaces. After serving as adjuncts to inscriptions the spirals became elaborated as sole patterns, at first with a few simple coils, and then elaborated with more coils or links, sometimes to a great length. The difficulty of designing good covering patterns out of true continuous lines probably led to the introduction of false links, and thus what would have been an opening in the middle was barred across, some beautiful effects being obtained by this false barring. The next stage is where continuous lines of spiral pattern are placed side by side and other patterns developed in the space between them. Sometimes the intervening patterns become so complex as to overshadow the mere spirals, as in the splendid ceiling of Neferhotep in the eighteenth dynasty. But the glory of Egyptian line decoration was in the quadruple spiral, of which the most elementary example is on a boat cover as late as the twentieth dynasty (Rameses IV.), though it has passed through this stage long before, unless this be regarded as a degraded simplification of it. From this was developed a peculiar pattern by the omission of the lines which define the spirals, reducing it to a system of rows of hollow-sided quadrangles without apparent connection. Then by introducing link lines so as to form a quintuple spiral, which was still more complicated by lotus flowers and buds in the hollows and recesses. Here the Egyptians had reached the limit beyond which more detail would be merely confusing. By careful use of colour to separate the various parts these complex patterns remain clear and pleasing in spite of their richness of detail. Another development of the quadruple spiral was formalising it into a torturing kind of design which can only be described as "cursedly ingenious." The fret patterns are all modifications of corresponding spirals, the cause of each change being obviously the influence of weaving. As early as the fifth dynasty we have a fret of rhombic form in basket-work in the screen behind the figure of Ptah-tanefer at Gizeh. The angles show that the plaiting was in

three directions; as is found in the basket-work pattern at Beni-Hasan. But frets in general are very rare until a late period, and doubtless depend on the adaptation of spirals to textiles. There is no trace of fret in the Mycenaean art, the spiral there being figured on stone or metal, while the women wore flounced dresses with scale pattern. But in the pre-Persian age fret-pattern weaving in borders was the standard design, as we see on the coloured robes of the Parthenon statues, and immediately after that the stiffness of square frets swarms over Greek art, to the exclusion of the graceful spirals and scroll borders. The source of chequer patterns is unmistakably in plaiting and weaving. On the oldest monuments the basket sign, *neb*, is chequered in different colours, so are also the baskets of farm produce carried by the servants as shown in the tombs. The modern Nubian basket-work is well known for the many patterns. The chequer pattern is found in every period in Egypt, and is perhaps most common in the latest forms on the sides of thrones in the Ptolemaic age. In the Middle Kingdom we find chequers covered with bars of colour, red and green at Beni-Hasan. Somewhat analogous are the network patterns, of which a fine example is on a horse-cloth of Rameside age. This design rose to importance when introduced as an architectural element in the decoration of columns at Tel-el-Amarna, coloured yellow, and the spaces alternate red and blue. Professor Flinders Petrie concluded by saying that the Egyptians had evidently no compasses, but used the string and points. The absence of a simple and self-evident motive like the sixth of the circle is very striking.

GENERAL.

Mr. John Morley, M.P., has been elected a trustee of the British Museum, in succession to the late Lord Bowen.

Mr. J. W. Clark, M.A., will, on the 13th instant, deliver the Rede lecture on "The Position, Arrangement and Fittings of Libraries during the Middle Ages and the Renaissance, with special notes on the system of Chaining Books," at Cambridge.

The Jury of selection for the forthcoming annual exhibition in Munich will consist, for architectural designs, of Professors A. & F. Thiersch, Hauberisser, Seidl, Von Schmidt and Bühlmann.

The Plans received by the Metropolitan Asylums Board in competition for the proposed fever hospitals at Hither Green and Tooting Graveney will be on view until the 6th inst. at the Imperial Institute.

Mr. H. A. Reid, in conjunction with his partner Mr. Green (both of Johannesburg), have obtained the first premium of 200*l.* offered by the Cape Town Council for the erection of a new town hall. The contemplated outlay, not including the upper part of the clock tower, is 50,000*l.*

Lord Mostyn has given a piece of land for the erection of a church in memory of the late Duke of Clarence at East Llandudno. Lady Augusta Mostyn has also given a donation of 1,000*l.* to the same object.

The Conversazione of the Society of Arts will take place at the Imperial Institute on the evening of Friday, the 22nd inst.

The Royal Archaeological Society will meet in Shrewsbury at the end of July next for their annual conference.

The French Archaeological Congress opened in the Town Hall at Saintes on Tuesday. About one hundred delegates were present, including several from Great Britain.

The Council of the Society of Arts offer a prize of 25*l.* for the best design for a silver cup. The design, if adopted, will be used for the Swiney prize for "The best published work on Jurisprudence." The value of the cup is 100*l.* The offer is open to all students of schools of art in the United Kingdom. Competing designs should be sent in not later than December 31, 1894.

Mr. Val Prinsep was, on Monday, elected a Royal Academician in succession to Mr. E. Armitage, who has joined the Retired Academicians.

The Scottish Society of Painters in Water-Colours have elected the following artists as honorary members of the Society: Joseph Israels, James Maris, J. M'Neil Whistler and Sir Edward Burne-Jones.

Mr. J. C. Rogers, secretary of the Surveyors' Institution, has been presented with a service of plate and a purse of 400 sovereigns, in recognition of his long and devoted services.

Mr. G. T. Brown, of Sunderland, having obtained the first prize in the competition for the Board School in Hudson Road, Sunderland, has been entrusted with the carrying out of the building. The second prize was gained by Mr. J. Eltringham, and the third by Messrs. Oliver & Leeson.

Sir R. Rawlinson was, on Tuesday, elected president of the Institution of Civil Engineers, in succession to Mr. Alfred Giles.

Mr. C. Barry has prepared plans for the new building of the Institution of Civil Engineers, and it is expected the work will be commenced early in the forthcoming recess.

The Architect.

THE WEEK.

AN ingenious attempt to nullify one of the most essential provisions of the Metropolitan Building Act was witnessed in the Queen's Bench Division on Monday. For thirty years police magistrates have had the power to order the demolition of structures that are declared to be dangerous by the proper officer or surveyor. When a case of the kind, relating to ten houses, came lately before the magistrate at Wandsworth, the point was raised that he could not make the order because it had not been shown that the brickwork in question was dangerous to passengers or passers-by. That it was dangerous to the inmates of the houses was assumed to be of no account. The magistrate declined to adopt that interpretation, as it would stultify his own decisions, for hitherto he had made the orders when it was testified that buildings were dangerous. He also declined to state a case. Application was accordingly made to Mr. Justice CAVE and Mr. Justice COLLINS for a mandamus to compel the magistrate to state a case. Their lordships upheld the magistrate's view. Taking the Act as a whole, they found that it comprised buildings that were dangerous to the inmates as well as to passers-by, and the argument that shoring was intended to assure the safety of the latter was met by saying that the protection was an *ad interim* one, while the structure was being taken down.

THE Society of Architects will this year visit the Rhine district and Bavaria. The members will leave London on July 27, and the first part of the excursion will comprise visits to Cologne, Andernach, Boppard, St. Goar, Mayence, Worms and Heidelberg, which will be reached on August 4. In the second tour Wurzburg and Nuremberg will be seen, and the return will be *via* Cologne, the party arriving in London on August 14. The price of a ticket for the first ten days, which will free the holder from London to Heidelberg and back, including second-class rail, first-class boat, and good hotel accommodation, will be 10*l.* 10*s.* A ticket for the seventeen days' tour will cost 15*l.* 15*s.* The prices are very moderate. As each member can introduce two friends, ladies or gentlemen, the excursion is likely to be enjoyable. The district selected contains many varieties of buildings, which should be seen by all architects, and the greater part of the country traversed is picturesque.

THERE was a meeting of the trustees of the National Gallery held on Tuesday, when the following resolution was passed:—"The trustees of the National Gallery cannot permit Sir FREDERIC BURTON's resignation of the directorship to pass without recording their high sense of the eminent services which he has rendered to the Gallery during the time that he has held that office. The trustees owe to him some of the most valuable additions that have been made to the collection, such as the Blenheim Raphael and the Holbein and Velasquez from Longford Castle, besides many other examples of artists previously unrepresented in the Gallery which are too numerous to record—additions which have placed the National Gallery amongst the first collections in Europe. By this arrangement of the pictures according to their schools he has added greatly to the usefulness of the gallery as a means of public instruction. The catalogue which he has compiled of the contents of the gallery, from its literary merits and knowledge of art history, has made it, perhaps, the best of any European work of the class. The trustees desire that a copy of this minute should be communicated officially to Sir FREDERIC BURTON." This tribute to a zealous officer was no more than was deserved, and it is well it should be put on record, for the late director of the National Gallery was not disposed to make the world acquainted with his labours.

THE scheme for the establishment of a school of architecture and applied arts in Liverpool is becoming more definite. It is proposed to constitute a special Board, formed of representatives of the City Council, University College, the Architectural Society, the Academy of Fine

Arts, the Master Builders' Association and the Building Trades Federation. The professor of architecture who is to be the director of the school is also to have a seat. The Board will have charge of the organisation, and make arrangements for establishing and upholding studios with teachers for modelling and sculpture, including carving in stone and wood, for mural decoration and glass-painting, metal-work, plaster-work, and any other art that is subsidiary to architecture. The courses of instruction on architecture will be given in University College. If considered requisite, classes will also be opened for teaching such industrial arts as pottery, goldsmith's and silversmith's work, bookbinding, typography, engraving, etching and lithography. As regards finance, it is understood that the Roscoe Professorship of Fine Art can be made part of the organisation, with of course the present income. Accommodation for the professor of architecture and his classes would also be provided in University College. Besides, there would be a revenue from the students' fees, the grants of the Science and Art Department, and the City Council. After allowing for all the money that would be likely to be obtained from those sources, it is calculated that 1,000*l.* a year would have to be provided from the rates. The technical instruction committee of the City Council are responsible for the scheme, and it obtained its endorsement by a vote of the Corporation on Wednesday.

THE Congress of the Union des Arts Décoratifs in Paris occupied no less than twelve days, apparently a long period if measured by the results. One of the resolutions adopted will, however, change the character of the society. It has been hitherto under the control of amateurs, and hence it was that so many efforts were made to set up the museum at a remote distance from the industrial quarters, where the examples could be turned to account. Henceforth designers, members of employers' syndicates and others engaged in manufactures can join the Council, but it remains to be seen whether they will care to give their support to an institution which must be pronounced to be a failure. What is necessary is the withdrawal of all the amateurs from the Council. The Congress expressed regret at the extent to which imitation is now carried on in French industrial art. As a remedy it was proposed that the Government should offer commissions for the decoration of public buildings, and for designs of other kinds, in which novelty should be declared to be indispensable. For that purpose it was proposed that special grants of money should be voted, and that the arrangements should be entrusted to competent men, who need not be officials. It was likewise recommended that in the public museums examples of art should not be placed in obscurity in order to make room for curiosities which are not interesting from their form or colour.

TWENTY-TWO sets of plans were delivered in the competition for the asylum at Winwick, near Warrington, which is to be erected by the Lancashire Asylums Board. The three which Mr. HOWELL, the assessor, considered as most deserving are those by Messrs. GILES, GOUGH & TROLLOPE (estimated cost 258,909*l.*, or 129*l.* per bed), Mr. G. T. HINE (222,164*l.*, or 111*l.* per bed) and Messrs. CRISP & OATLEY (300,200*l.*, or 115*l.* per bed). They will be considered by a committee of the Board. The premiums are 200*l.*, 150*l.* and 100*l.* The buildings are to accommodate 2,000 patients (chronic lunatics and imbeciles), namely, 1,000 males and 1,000 females, with administrative offices. Provision has also to be made for receiving-wards to accommodate 50 excited patients of either sex and 200 sick and infirm of either sex. The architectural character of the building (which, it was suggested, should be simple and without superfluous ornament), as well as the grouping of the parts on the plan, was left to the architect. The chief points upon which the Board insisted were soundness and economy of construction, with completeness but simplicity of design, economy with reference to working and supervision, convenient arrangement of internal communications with regard to levels, &c., and a general conformity to the instructions and suggestions for the construction of asylums issued by the Commissioners in Lunacy.

ARCHITECTURAL ESSAYS.—II.*

IN his second essay, "Conscience in Architecture," Mr. VAN BRUNT treats a theme which is closely related to the subject which gives the title to the volume. He does not, of course, mean to hint that fees are sometimes excessive or that builders are allowed too much laxity in creating extras. By conscience he recommends something corresponding with the exploration of their interior world, that darkest of continents, which good people periodically undertake, and as they believe with advantage to themselves. In a process of that kind there must be a moral standard. Suppose a man sets before him the example of a neighbour who at all costs keeps a good cook, a carefully-selected cellar, and is faithful to the duty of frequently collecting friends and acquaintances at his table, it is easy enough for a lover of virtue to test how far he corresponds with so excellent a model. But if he set up soon afterwards another virtuous man for imitation, who believed that digestion and economy were aided by solitude, and that good dinners shortened life and weakened the ethical sense, our neophyte's progress along the path of virtue would be erratic. Mr. VAN BRUNT believes that architectural progress is also hindered when there is not fidelity to one standard. According to him, "the Greek architect of the time of PERICLES had before him a fixed and sacred standard of form," the Mediæval builders had also their revered patterns, and "so it was even after the period of the Renaissance." But of us it is said how in our degenerate days "at the same moment we are designing and painting Greek vases, decorating Japanese screens, constructing furniture according to our reminiscences of the Gothic of the EDWARDS, or the Renaissance of the JAMESES, of Queen ANNE, or of the GEORGES," &c., and "it would seem, in fact, as if our knowledge, our ingenuity, our industry had swamped our art." Mr. VAN BRUNT therefore concludes that we require "the establishment of principles, and not forms, as standards of excellent work," and a recognition of the fact that "the very finest result of high culture, in architecture as in literature, is to utter thought with simplicity."

It seems to us that, in longing for the return of vanished ideals, Mr. VAN BRUNT is not an exponent of the American idea. His countryman EMERSON was more expressive of it when he said "dedication to one thought is quickly odious." We can never have the conditions of life which prevailed in Greece and in Mediæval Europe. The artists of those days might be described as mentally belonging to a ruminant class. Their horizon was circumscribed, and they could calmly and placidly keep on revolving a few thoughts or fancies. In an age when the great globe itself is not considered large enough to satisfy human inquisitiveness, and the light from stars millions of miles away is analysed as prosaically as if it had something to do with an obstruction case in a City alley, men cannot be expected to have "a sacred standard of form" any more than a sacred star-spangled banner or a sacred schedule of import duties. We are all only a sort of flotsam and jetsam on the waves of time, and we cannot resist the impulse which keeps us floating. When so many things are unstable, how can it be expected that architecture alone is to remain unmoved? Or, to put the case in other words, it may be said that earlier in the century science was satisfied with examining the phenomena of the world that is external to man. Now it is man's turn to be investigated. All his beliefs are put under the microscope. It is no longer enough to say that forms must be adopted because they were held sacred by Greeks or monks. Their fitness for common wants must also be demonstrated as well as their omnipotence. That is a slow operation, and until it is accomplished fancy may well be allowed to find enjoyment in dallying with forms which are attractive because they are not sacred. At some future period there may be more wisdom, and architecture, like ULYSSES, may have a spell of the "soft serenity of age," and a return to old beliefs or superstitions, but at present there are no signs of it. Before it is reached men will probably have to discover that universality is a delusion, like many others in art.

His conclusions lead Mr. VAN BRUNT to consider the influence of the personal equation in architecture in another

essay. Unfortunately, there are not enough materials for the investigation of a question of that kind. To comprehend the personal equation we must know something of the lives of architects, and that knowledge is not forthcoming. The most that Mr. VAN BRUNT can say is that the decorative or ornamental part of buildings sometimes varied according to periods with which the names of certain kings and queens are associated:—

When architecture had ceased to be a structural evolution, and was based upon a formula of pilasters and entablatures, enclosing impostes and arches, decoration or ornament assumed a function until then unknown, and there was a distinctive style corresponding to the character of each reign, often contrasting with curious abruptness. Thus we recognise a style of Francis I., free, elastic, poetic, romantic; of Henry IV., bold, coarse, grotesque; of Louis XIV., full of grandeur without, of pomp and splendour within (Viollet-le-Duc has called it "the New Renaissance"); of Louis XV., frivolous, licentious, ostentatious, rococo; of Louis XVI., decent, orderly, pure to prudishness; of the First Empire, a theatrical display of imperial Roman proprieties, meagre and tarnished; of the Second Empire, elegant but profuse and luxurious, drawing its *motifs* from every historical source, but harmonising them with a fastidious, academical spirit, not unconscious of the purifying and ennobling influence of the newly-discovered Greek principles of art—a style of to-day, too near us to be recognised now in just perspective, but for which our French contemporaries will be held responsible in the next century. So there is a style of Elizabeth, of the Tudors and Stuarts, of Mary, of Anne, of the Georges and of Victoria. So also in Spain the enthusiasm, the efflorescent splendour and pride of Ferdinand and Isabella and of Charles I. are clearly expressed in the joyous and sunny exuberance of the architecture of their times. But in the time of Philip II. there was promptly substituted for this brilliant manifestation a cold, academical formalism in full sympathy with his iron rule.

The personal equation, which consists in a general combination to produce a style that will be more or less gratifying to a ruler, is not a surprising exercise of individuality. In all times it would have been easy for a critic to complain that architects were running in one groove. If it were otherwise there would be no chance of becoming acquainted with the history of styles. The varieties of buildings are comparatively few, because there was always a tacit understanding that it was better for everybody to restrain inventive power. The old Greeks, as well as the English architects of the nineteenth century, accommodated themselves to that view of duty. Mr. VAN BRUNT, who would gladly support 'originality and the utterance of thought with simplicity, is compelled to own "that the present and future architecture of all civilised nations must, unlike that of all primitive peoples, express not so much the natural man as the artificial or conscious man." He might have added that as man must be considered not only as an artificial or conscious individual, but as a mere unit in a multitude, he has a double set of duties to perform, and that when he is building he would often do well to generalise his occupation, and in that way express the common tendency of his contemporaries.

The next essay in the volume has the Château of Blois for subject, and contains an excellent summary of the lessons which can be derived from that valuable work, which represents the transformations of architecture during five centuries. We lately published some large photographic views of the buildings, including the beautiful open staircase, which Mr. VAN BRUNT describes as "a useless *chef-d'œuvre*, which never could have been built in a settled and serious age; but the joyous new birth and enfranchisement of the mind, which were then filling all the corners of Christendom with inspiration and light, could not have their due record in architecture with any less ebullient demonstration."

The essay on the "Present State of Architecture" corresponds with a great many others on the subject, which seem to be inspired by the man who travelled from Dan to Beersheba, and found it all barren. A sort of exception is made in favour of French work, but we are told "its blossoms invariably die in crossing the English Channel, and when imported to this [the American] side of the Atlantic, there is little left of it but branches and withered leaves." In England Mr. VAN BRUNT considers we are too much given to reviving completed systems which can be adapted to new uses without much change of the old characteristics. But is not all evolution a transformation from one form of completeness to another, just as the kaleidoscope patterns are made to change when most perfect? The only rational theory of Gothic is that which

* *Greek Lines and Other Architectural Essays.* By Henry Van Brunt. Boston and New York: Houghton, Mifflin & Co. London: Gay & Bird.

regards it as a modification of Romanesque—a discovery for which HEINRICH HEINE deserves some credit, for at a time when experts believed in the sylvan origin of Gothic arches he perceived from what he saw in St. Sernin, Toulouse, “die Entstehung des Gothischen Spitzbogens aus dem römischen Kreisbogen.” In the process of change from the older to the newer style the architects may have been charged with acting wrongly by too faithful an adherence to old characteristics. The history of the changes of style must always remain obscure, and it is not everybody who would agree with Mr. VAN BRUNT in believing that the late Gothic revival is to be ascribed to the operation of the moral sense, which demanded truth in art. As regards Queen Anne, it is said that “if the genius of NORMAN SHAW struck the first blow, the genius of THACKERAY gave the movement inspiration and character. Both revivals were patriotic, and would have been impossible if not associated with phases of English history; but neither conscience nor historic sentiment nor patriotism can make art.” Mr. VAN BRUNT owns that in America they have not developed old forms more happily than in England, but as architectural schools have been established he has hopes that they will be able to profit by the conventionalities of the Old World without being bound by them. What was done by HENRY HOBSON RICHARDSON in handling Romanesque should inspire confidence that similar attempts will hereafter be witnessed. If that expectation can be realised, English architects will be among the first to rejoice. But whatever may be accomplished, it is the conclusion of Mr. VAN BRUNT that a new style worthy of a place among the great historic styles is impossible.

The last essay treats of “Architecture and Poetry.” In it he renders justice to many Englishmen, and his praise of LONGFELLOW is fully merited. It cannot, however, be expected that poets could employ technical language with ease; indeed, one of ADDISON’S objections to MILTON is on account of the introduction of terms which would not be understood at tea-tables, and without technicalities a precise description of an architectural work is impossible. Mr. VAN BRUNT, with hesitation, presents some verses, entitled “The Church Door,” which may have been inspired by the porch of St. Trophème, at Arles, as an experiment in which the most expressive words are not rejected through fear of the critics. Here is a sample:—

The narrowing arch is deep and wide;
Niched in its jambs on either side,
Shaft beyond shaft in ordered stare
Stand on their solid stylobate,
Their leafy capitals upholding
Archivolt and fretted moulding;
Arch within arch with lessening leap,
From shaft to shaft concentric sweep,
Echoing inward o’er and o’er,
Inward to the vaulted door,
Every arch by subtle hand
Wrought with roll or bead or band,
Wrought with fillet or with fret,
Dentil, billet or rosette,
While between the sculptured rings
Angel choirs spread their wings,
And, soaring as the arches soar,
With viol and with voice adore.

For the happy masons said,
As the radial stones they laid,
Truly wedged, with every joint
Loyal to the central point,

And by touch of chisel taught
Utterance of human thought,—
“Let the choral arches ring
Joyfully a welcoming,
Every one in concord fair
Moulded and attuned to share
By the cunning of the mason
In a solemn diapason,
While the great arch over all,
Silent, bears the mighty wall;
Silent, while its arch-stones deep
Under the sheltering label sleep,
And the corbel-heads intone
Vespers with their lips of stone.”

Then with reverent hands they laid,
Deep in the archèd frame embayed,
Circled with immortal song,
Upon a lintel deep and strong,
A sculptured slab, to symbolise
Grace divine to human eyes.
Oaken doors they hung below,
On forged hinges turning slow,
The rigid iron branching wide
With foliate growth from side to side.

General readers may prefer the verses with a similar title which ARTHUR PENDENNIS turned out without much exertion, but in that case the masonry was of no more account than the frame of a picture, while in Mr. VAN BRUNT’S lines we can see the stonework and enjoy the mysterious carving.

The “Church Porch” is evidence of literary ability that Mr. VAN BRUNT should more often exercise. An architect who appears as an author and treats of art is expected to reveal new discoveries, and a man who has not a message which can be turned to account in everyday practice receives a cold sort of welcome. If that rule were applied generally, there would be few books produced. It

is often an advantage to be told of our imperfections, and a writer who considers the subject far away in Kansas City ought to have the credit of being impartial in his reproofs. Mr. VAN BRUNT is in a position to take a view of the art that is not enjoyed by all critics, and if from his coign of vantage the processes of the Greeks appear more interesting than those of his countrymen and their relatives, it is not unlikely that the critics of the next century, who are sure to have still more acquaintance with transforming processes, will hold a like opinion.

ORNAMENT IN BIRMINGHAM.*

THE efforts which are being made in Birmingham to undo the ill-effects of the teaching of the Science and Art Department—which were almost ruinous to the local industries—are watched with attention by rivals as well as friends in France and Germany as throughout Great Britain. On that account everything which exemplifies the new system of instruction is sure to receive more than the average amount of consideration. Mr. JACKSON’S “Lessons on Decorative Design” afforded a glimpse into what passes in the classrooms, and his “Theory and Practice of Design” is a revelation of the instruction given to the more advanced students. We must say the latter book is satisfactory on several accounts. In the first place, it is evidence that although Birmingham suffered much from the weakness of the Governmental system, and in consequence the City Council would have been excused if they insisted that every lesson must have a direct reference to the trades of the city, there are no narrow views taken of the province of industrial art. There is a part of the book which relates to “vessels of capacity, cups and vases,” and in other parts various kinds of metal-work come up for treatment; but all that is allowable. A designer who wished to work in Birmingham would find much that would be advantageous to him in the pages, but they would be also useful to him if he selected a different centre of industry for the exercise of his skill.

The importance ascribed to architecture would by itself be almost a sufficient corrective of any desire on the part of a student or a committee-man to restrict design within too narrow limits. The following passage on the relation of the art to ornament, if found in a book by an architect would probably be considered as presumptuous, but Birmingham manufacturers will do well to respect the theory it expresses:—

Architecture, rightly understood, is the art of æsthetic construction—not construction merely, but construction allied with beauty; not made beautiful by superadded decoration, but by beauty inherent in its construction. In architecture we recognise the fullest expression of the inventive and constructive faculties, together with a regard for beauty; and, as it is based upon order, fitness, proportion, stability and grace, elements drawn from such a source necessarily possess qualities so high as to command the attention of the ornamentist. The chief concern of decorative art is with beauty of line, form and colour, and it has less to do with constructive necessities than architecture. The freedom it enjoys from that restraint which attends æsthetic construction is, without some counteracting influence, a dangerous liberty, liable to run riot; but the employment of architectural elements offers a means for minimising such a tendency. In all the best periods of ornamental art the influence of architecture is distinctly seen. It is traceable in pottery, stained and painted-glass, ironwork, jewellery, the decoration of panels, pilaster shafts, &c. Architectural forms, pure and simple, are often incorporated in decorative designs, but are oftener modified by the imagination, so as to bring them into harmony with other and freer details with which they become associated. Hence while some forms are distinctly architectural, others are but suggestive. Now, in adapting architectural forms in a design it is not essential that the rigidity necessary in pure architecture should always be maintained, because the same structural conditions have not to be dealt with. In the case of architecture, actual physical weight has to be provided for, in decoration the appearances of weight only; and so long as the eye is satisfied with the semblance of stability, freedom of treatment can be indulged in. The reason given above for modifying the severe forms of architecture, namely, that they may be brought into harmonious relation with more ornate elements, justifies such treatment; and the history of architecture itself furnishes instances in which forms, taken from a severe style to be used in a richer one, underwent considerable change to fit them for their new position.

Respect for architecture will help to check extravagance in a designer, and also will enable him to overcome a petty manner of treating forms. Mr. JACKSON takes care, how-

* *Theory and Practice of Design: an Advanced Text-book on Decorative Art.* By Frank G. Jackson. London: Chapman & Hall, Limited.

ever, to point out how far the architectesque character of ornament is to prevail. By contrasting the treatment of wall-surfaces and of textiles for hanging in rooms the difference in the application of ornament according to purpose appears obvious. For neither class of work is the adoption of naturalistic forms recommended. Although imitation of Japanese designs is common enough in Birmingham (and indeed some people imagine that the imitations are so close they can pass as Eastern products), in the Municipal School the style does not obtain much favour. When Mr. JACKSON says that "Modern decorative art has been made so to depend upon natural objects for its material, it is in constant peril of losing its essential characteristics," and that "the principle of irregularity, the chief characteristic of the picturesque, has been unduly emphasised, to the almost complete neglect of the principle of order, which is the basis of decorative art inherited from construction," we imagine that many members of the Council would not agree with him. The unavoidable reaction against South Kensington has compelled people in England to look with favour on a naturalistic treatment more or less corresponding with the style of the Japanese, and it is found that by attention to framing lines or borders the irregularities can be made to appear less disorderly than might at first be supposed. Mr. JACKSON is, however, consistent in what he says. As we have seen, he prefers an architectonic basis for ornament, and it is not always easy to reconcile Japanese realistic or naturalistic treatment with that sort of regulatory influence. As the book is dedicated to the memory of the late F. W. MOODY, it corresponds with what he taught, or, in other words, upholds the supremacy of the Italians as ornamentists. Those who prefer a more flexible style, for surface-decoration especially, will, however, admit that, as a corrective of what used to be known as "Brummagem art," there can be nothing found that is more effectual than a study of examples of the best period of Italian Renaissance. Another advantage of the Italian style is the more general applicability, for it can be employed in sculptural decoration, especially where the figure has to be an element, a property that must count for much wherever metal-work of a high class is produced.

In at least one way, however, Mr. JACKSON draws a lesson from the practice of the Japanese, and that is in the general use of the brush for outlines as well as washes. When treating of methods of expression he says:—

While our national scheme gives, perhaps, too much encouragement to line-drawing, it gives no stimulus to space or mass-drawing by the brush. This omission is to be regretted, as practice of this kind bears so directly on many artistic industries. The use of the brush is capable of developing powers of drawing beyond all other means, and while it will assist the student to more rapidly appreciate the value of quantities by directing his attention to spacing and to the solidity of the forms used, the freedom of hand acquired by the employment of the brush will affect his line-work and raise its quality. Whatever may be thought of the Japanese as decorative designers, there can be but one opinion as to their merits as draughtsmen, and their skill in drawing is largely due to their being accustomed from their youth upwards to the use of the brush as a writing and drawing implement. The power seen in their line-drawing, which for vitality is much superior to the generality of European work of a similar nature, has been developed from the restricted use of a hard point. In his Oxford lecture on "Line" Mr. Ruskin, after speaking of the practice of the old masters, says, "The fact is that while we have always learned, or tried to learn, to paint by drawing, the ancients learned to draw by painting. The brush was put into their hands when they were children, and they were forced to draw with that until, if they used the pen or crayon, they used them with the lightness of brush or the decision of a graver." By substituting the brush for the pencil-point we have a direct means for expressing mass and space as well as line. Linear ornamental elements translated by the brush become enriched and gain special characteristics by the process; lines so changed and forms which are the natural outcome of the implement not only largely increase our range of ornamental material, but also augment our methods of expression.

The numerous illustrations prove that Mr. JACKSON is as expert with the brush as with the pen, and he is able to speak with experience of the different implements used in drawing. But he does not confine himself in his teaching to representations on the flat for surface decoration; his remarks on ornament in relief and in the round exhibit no less competence, and it is evident he is well qualified to supply all the information concerning art which Birmingham is likely to require—an amount which is not easily attained or systematised. From the practical necessities which inspired the lessons, Mr. JACKSON's book can be recommended for use wherever art is combined with industry.

EGYPTIAN DECORATIVE ART.

IN his second lecture on "Egyptian Art and Decoration," delivered before the Royal Institution, Dr. W. Flinders Petrie said that it might be supposed that the imitation of natural forms would be the earliest system of decoration; it was not so. On the contrary, the geometrical forms of wave lines and chequers copied from weaving and the varieties of the spiral were the first ornaments of importance, feathers and flowers coming at a later period. The feather in its different forms is shown unmistakably on the coffins of the Antefs in the eleventh dynasty before coming into common use. The royal mummy is seen swathed in protecting wings, representing those of Isis behind him and of the vulture of Mut on the head. On the kings of the eighteenth and twentieth dynasties we often find a wide belt covering the whole stomach with the scale pattern, and this in non-warlike scenes, where no defensive scale armour would naturally be shown. Such a belt would be admirable for lightness and warmth, and it is absent in fighting representations. This feather pattern is also often used on the sides of thrones from the eighteenth dynasty to the latest times. Later it is seen on very incongruous objects. In the eighteenth dynasty it is used around columns (Tel-el-Amarna) and on metalwork, where it must be a purely artificial marking. Under Seti I. it became elaborated with markings both on the dress of a god and on a throne cover. Under Rameses II. it was degraded into an unintelligible pattern, as on the dress of the god Amen; and later at Philæ on columns, in an inverted and very corrupt form. The use of flowers for ornament is so natural that they occur in earliest times, although only a few were used—the lotus first, and then the papyrus, the daisy and the convolvulus, the vine and palm; these almost complete the material of vegetable design. The rosette may be called a generic flower ornament, so conventionally treated as hardly to receive a name. In the eighteenth dynasty, e.g. it is a daisy, more seldom it has the pointed petals of the lotus, and it fluctuates so between the geometrical and the natural as to defy detail. One cause of this is the effect of leatherwork. The coloured leather funeral tent of Isimkhat found at Deir-el-Bahari opens our eyes to a great deal. There is an elaborate design, descending to long inscriptions of small hieroglyphs, all worked by cutting and stitching leather. The earliest rosettes we know—those on the headbands of Nefert—are plain discs of colour divided into segments by white lines across them. The discs are leather secured by radiating threads, and the same appear in the eighteenth dynasty more varied by concentric circles of colours. Another stitch ornament is seen on the stuffs used for covering thrones—star and cross patterns, and in the spaces discs of colour with white pieces sewn on round the edge. On a dress of Rameses II. are little six-pointed stars. Some rosettes are independent of the influence of leatherwork. The great series of these is in the moulded glazed ware of Tel-el-Amarna, where we have several dozen varieties. On metal vases the rosette is very general, sometimes a separate ornament of beaten work rivetted on, like the silver ox-head at Mycenæ, or embossed *repoussé* on the metal. Rosettes are found carved in wood or ivory, and along borders with the lotus or other subject. One pattern is the disc surrounded by spots, much used on early Greek and also found in Ægean pottery, although rarely in Egyptian design. It is seen on the negroes' scarves and on the dress of Amen; and it appears to be distinctly a foreign ornament. Dr. Petrie said he now came to the lotus, so widely spread that some have thought it the source of all ornament; and there is certainly plenty in it to tax the imagination and reason. The debated question of lotus and papyrus appears to be resolved by the flowers with long sepals and petals being the lotus, and the bell-flower with short sepals being the papyrus. In ornament, doubtless, they were sometimes confused and the details mixed, and it is of no use trying to separate them. The oldest use of the lotus was in groups of two flowers tied together by the stalks, such as are found on the prehistoric pottery at Koptos and on the earliest tombs. The plain flower was used very early; it is seen on the head-band of Nefert, in the fourth dynasty. In the tomb of Imery, of the fifth dynasty, it is seen as a capital in wood. The variety of lotus capital is very great; the bud capital and the opened flower are both shown in the eighteenth dynasty, and many complicated and impossible forms in the decadent age of the Ramesides. The lotus was much used in repetition as a border-pattern, but not before the eighteenth dynasty. The flower and bud were developed in mechanical fashion, but the isolated *antheion* (which is so much like this) has probably a different origin. The whole plant was also a favourite subject as a group. It is seen as a foreign ornament on the dress of a Syrian slain by Rameses II. at Abu Simbul, but perhaps the tufted papyrus is intended here. The Ptolemaic walls are ruled over with stiff friezes of lotus and bud. The flower now becomes a monstrosity, only decorative and not natural. First there is the *fleur de lys* type, with curled-over sides and a middle projection. The Egyptian drew the interior or top view of an object above the side view, and

partly in top view above that. A dish would be drawn in side view and a top view of its contents placed over it, and the bunch of flowers that lay on it placed over the top view. Thus we see that the projection in the midst of the lotus flower is the third sepal at the back of the flower, the fourth in front being so foreshortened as to disappear altogether. A more complex form comes next and has not been yet explained. In the eighteenth dynasty a strange form is seen with reversed curling arms above the calyx, from which we get a very mechanical form greatly developed in Assyrian and Greek types of the pattern. If it can be proved that the Assyrian tree pattern is earlier than this development, we could grant what seems a likely influence on this development of the pattern. In Assyria this became a staple design, in which the top was greatly increased at the expense of the lotus sepals below; but still the four sepals, two front and two back, are shown. In the Greek designs the same elements remain, however barbarous they may seem in comparison. A late development of the lotus in Ptolemaic Egypt was with a central spike through the fan of petals. On very compound lotus patterns there is a pendant from each seed of the side petals; but this does not appear till the eighteenth dynasty on the monuments; it is sometimes single and sometimes double. But here, as in the spirals, the scarab type is earlier than the architectural. It is a mere monstrosity in the latter view; while in a scarab of green jasper, which from the style and material seems certainly of the eighteenth and probably of the twelfth dynasty, there is an already conventional lotus group with the four sepals and inner petals developed into a sort of tree pattern. The papyrus was often confounded with the lotus in decoration by the ancients as well as by moderns. It is well shown in the group of boat-builders to whom bundles of papyrus are being brought in the fourth dynasty tomb of Shepserkan. The lotus and papyrus are shown alternately on the frieze of Amenhotep III. The two plants are also contrasted on the two granite pillars of Tahutmes III. at Karnak. Much use was made of the papyrus in the floral work at Tel-el-Amarna. On the painted pavement groups of papyrus with large and fluffy heads of seed vessels were figured, and on the coloured tiles the landscape view of the papyrus plant is frequent. The palm, though the most important tree of the country, had little effect on architecture, there not being a single example of columns copied from a palm-stem. In later times the branches and fruit were both sculptured. The vine is one of the oldest cultivated plants in Egypt, and all the designs from it are based on the idea of its climbing and trailing over the houses. It appears mainly in the floral work of the eighteenth dynasty. Ceilings painted golden yellow often have vine-leaves and bunches of grapes. The convolvulus has not been much acknowledged as an Egyptian ornament, but it often occurs during the eighteenth and nineteenth dynasties. Dr. Petrie went on to speak of the artificial combinations of flowers, and concluded by a reference to the men and animals shown in decoration. The men were often represented with captives kneeling at their feet. Of the animals the ibex does not occur till the eighteenth dynasty, but is often found on finger-rings of Akenaten's time. We have also the hawk, the vulture and the duck. The lecturer concluded by saying that our theory of an artistic effect which must never involve falsity, but which may have little or nothing to do with nature, was entirely outside the Egyptian's æsthetic.

THE LATE WALTER F. K. LYON.

THE late Walter Fitzgerald Knox Lyon was a son of Lieutenant-Colonel Lyon, 2nd Life Guards, and was born at Pau, France, in 1845, his godfather being the last Sir Walter Scott, son of the poet and novelist.

Having strong artistic inclinations and a great admiration for ancient buildings and antiquarian research, he determined to follow the profession of architecture, and entered as a pupil the office of Messrs. Peddie & Kinnear, of Edinburgh. Here he spent several years, during which he visited, studied, sketched and measured many ancient castles and buildings in different parts of Scotland, thereby gaining an intimate and exceptional knowledge of Scotch Baronial architecture and became an expert master of the style, as is shown by numerous executed works.

Commencing practice in London in 1869, he was successfully engaged in the erection of large country houses both in England and Scotland, notable among them being Pendley Manor House, near Tring, Herts; Cowhill Tower, Dumfriesshire; Fyndynate, Perthshire; and Kirkwood, near Lockerbie, together with a number of other works in which his architectural abilities were manifestly displayed.

A fine drawing of his, showing a suggested restoration of the south front of Edinburgh Castle, was some years back hung in the exhibition of the Royal Scottish Academy, and attracted much attention, being afterwards published in the professional journals.

He made occasional contributions to the papers of the Society of Antiquaries of Scotland, the last, in 1893, being on "The Structural Remains of the Priory of Pittenweem, with Plans and Descriptions of the Caves Below." He also took great interest in heraldry and genealogy, and was a clever etcher.

He was a Fellow of the Royal Institute of British Architects for some years, a member of the Conservative Club in St. James's Street and several golf clubs, where his kindly, genial nature and keen sense of humour made him a general favourite with a large circle of friends, and to those among them who had the pleasure of his intimate friendship his untimely death will prove a great loss.

He died on Monday, May 28, at his residence, 7 Redcliffe Square, S.W., after an illness of only six days, caused by chill, resulting in pleurisy and pneumonia.

ARCHITECTURAL ASSOCIATION DINNER.

THE annual dinner of the Association, which was held at the Holboin Restaurant on Thursday, the 31st ult., proved most successful as a social reunion of members and friends, when about seventy gentlemen sat down under the presidency of Mr. E. W. Mountford. There were present, amongst others, Mr. F. C. Penrose, Mr. Walter Crane, Mr. A. B. Pite, Mr. A. Cates, Mr. H. W. Barnes, Mr. F. T. W. Goldsmith, Mr. Paul Waterhouse, Mr. C. R. Ashbee, M.A., Mr. W. D. Caröe, M.A., &c. After the loyal toasts the President proposed "The Royal Institute of British Architects," and expressed the thanks of the Architectural Association for the aid given them in carrying out their examinations.

Mr. A. Cates, in responding, spoke of the value of the alliance of the Societies formed to promote the study of architecture, as by doing so students in the provinces were put on the same level as those who studied in London. He hoped that in the future they would establish a progressive examination, to be followed by an honours examination.

Mr. E. T. Hall proposed "Success to the Architectural Association." They had omitted that evening from their toasts the Army, Navy and other forces, and substituted the more peaceful and more important branch of the art of construction. That art was associated with the peaceful progress of society. They had a corporate existence, which enabled one to help another. The Association represented the youth, energy and zeal of the members, and it had a promising future before it.

The President, in responding, said the Association had done a great deal of good within the last quarter of a century of its existence. They numbered members in all parts of the world, and they had been copied in many distant towns in their corporate existence. Their number of members had risen to 1,200, and they were all paying members. The ranks of the Royal Institute of British Architects had been largely recruited from the Association, and he hoped in the future that the Institute would be made up almost entirely of A.A. men.

TESSERÆ.

Recipes in Art.

SOME ingenious artists have endeavoured to account mechanically for the superior perfections of the celebrated Greek statues, by the characteristic nature of lines and angles, uniformity and variety; and they have reasoned after the following curious manner:—That perfection consists in the variegated composition of straight, convex and concave lines and angles; that the straight gives simplicity, the convex greatness, and the concave elegance and lightness; that the waving line gives beauty, and the serpentine or twisted grace, that the Apollo Belvedere is composed entirely of very gentle convex lines, of very small obtuse angles, and of planes or level parts; but the soft convex predominates. It being necessary that the character of this divine figure should express force, grandeur and delicacy, its author has demonstrated the first by the convex contours, the second by their uniformity, and the third by the waving lines. The obtuse angles and light inflections form the waving line, and by their union is shown sufficient force and dignity. In the Laocöon the convex lines predominate, and the forms are angular, as well as where they indent or fall in as where they swell out, by which means the agitation of the expression is manifested, because in this way the nerves and tendons of the figure, which are much strained, are rendered more visible, the straight lines being opposed to the convex and concave, by which is shown that the figure is agitated. The sculptor of the Hercules has found out a taste altogether different; he has made the forms of the muscles convex and round to show that they were real flesh, but the line of indenting or entry is straight, to signify that

those parts were nervous and meagre, and by this is expressed the character of force and strength. In the Gladiator there is a mixture of the forms of the Hercules and the Laocoon, because the muscles in action are agitated and those in repose are short and round like those of the Hercules. In the torso of the Belvedere, a work merely ideal, all the beauties of the other statues are united because it has a variety so perfect that it is almost imperceptible; its plane or flat parts are not to be discerned but by comparing them with the round, and these with the other. The angles are less than the flat or the round, and could not be distinguished were it not for the little beds of which they are composed. Perhaps these rules may be of some use in the arbitrary conjunctions of composition, but they appear to be very inconclusive and much out of their place when thus applied to prescribed forms, which can result solely from their propriety and fitness to the character, and from actions corresponding with the sentiment and occasion. Besides their utter inapplicability, these multiplied little rules seem likely to generate manner, to substitute the artificial in the place of the natural, and to distract or occupy too much of that attention which ought to be bestowed on matters of more importance; and still further, they appear altogether unnecessary, for when these higher matters of the character and action are properly attended to they produce all that can be sought after by any rules without the incumbrance of their application; for instance, the character of a beautiful female, or of an athletic male body, and all the circumstances of its action, as sitting or dancing, being judiciously determined, the form of all the parts, their relative swellings, cavities, angles or planes must follow necessarily, and in their precise and exact degree; their conformity with the character and action is the only arbiter that can be admitted, and nothing is left to the choice of the artist. The contour of a stretched-out arm must depend upon the character of the arm, whether it be that of an Apollo or a Hercules, and upon the business about which it is employed, whether pushing or pulling or merely stretched out—for in all these cases the contour will be essentially different; the same must inevitably hold of all other characters and actions.

Grouping in Painting.

That the whole of the composition may with ease and pleasure to the spectator be comprehended in one view, it is necessary that its several parts (however variegated in their details) be so artfully linked together as to form one general appearance, consisting of a few large parts, masses or groups of objects. But whether the several parts of this concatenated mass be on the same or on different plans, it is equally necessary that although they be so united as to form an easy concurrence into one general view, yet they are not to be crowded or huddled together; their separation and distinctness from each other are objects of no less consequence than their union. The several portions or masses of this general appearance should be diversified either in their magnitude or figure, or some in both. Of these masses one ought to be principal, and all the others dependent and subordinate; and as the attention will therefore necessarily centre on this principal mass, it follows, of course, that whatever is intended to be of the greatest interest in the composition will appear more properly, and to the greatest advantage, as forming the whole or a part of this principal mass. As to the general shape or form of the principal and its subordinate groups, taken together, whether it incline to the pyramidal, either erect, inverted, laterally, or horizontally placed, or to any other figure, this is a matter entirely arbitrary; the only attention employed on this occasion is to guard against the too great regularity, sameness and equality of parallel, rectilinear, rectangular, or even too circular appearances. In a word, whatever be the general figure of these concatenated groups, it should neither be too regular nor too complicated, and it is rather to be loosely or obscurely indicated or hinted than clearly and specifically defined. The several parts of this concatenated mass should preserve some kind of equilibrium and symmetrical order amongst themselves, that nothing may appear wanting to its completion as a whole; and in the same manner that the several masses or groups are attached to each other, that nothing may appear entirely insulated or detached in all its parts, the several figures and other component parts of a group must in some part of its contour or drapery be, as it were, let into or interwoven with the next object.

Chiaroscuro in Architecture.

When the examples of beautiful and majestic arrangements of relative magnitudes and forms in architecture were once executed, they might be easily copied and multiplied by the rule and compass of mere mechanics; but the history of architecture and architects, both in Greece and Italy, affords one continued chain of proof that all the great inventors, restorers and improvers of architecture were, as might naturally have been expected, painters or sculptors. The first architect mentioned by Vasari is Buono, a sculptor and architect of the twelfth century. The Campanile at Pisa was com-

menced by one Guglielmo, and Bonanno a sculptor; the next architect mentioned by Vasari is Marchionne, a sculptor of Arezzo; the next are Jacopo a German, Lapo, and his pupil, the celebrated Arnolfo di Lapo, who commenced the cathedral of Florence. These were followed by Fuccio, Niccola and Giovanni Pisano, Lino of Siena, Margaritone of Arezzo, and Giotto, all sculptors, and the two last painters also, as well as architects. Agostino and Agnolo of Siena, Andrea Pisano, Orcagna, Brunelleschi, Michelozzi and Julian da Maiano were likewise all celebrated sculptors as well as architects. The history of architecture reveals the utility and importance of chiaroscuro, and the absolute necessity of its being a leading consideration in the fabrication of all objects presented to the sight. Attending only to the actual fact, without entering into the reasons or the necessities which might have occasioned it, we must confess that many of our churches and public buildings of the last age have the same bad appearance as Chinese pictures, where there is no light and shade to give brilliancy, repose and majesty of effect; mere walls inlaid with pilasters or half-columns, unconnected perforations for windows and doors, and nothing to relieve the sight from a dull disgusting monotony of light without shade. This hateful, insipid uniformity cannot be removed by diversifying forms on the same surface, like mere outlines on paper. They want the force of chiaroscuro to give them that rilievo which the sight necessarily demands, and without which they are not forms but sketches and indications of form. In the sound examples of art, when pilasters or half-columns have been employed, and consequently the entablature deprived of its accustomed projection, they were either accompanied with arched ways, which produced the necessary quantity of shadow, as in the Theatre of Marcellus, the Colosseum and many others, or their continuity was interrupted by other more retired parts or objects, to which they serve as illuminated portions or masses. Where prominent parts could not be obtained for the projection of adequate shade, voids have been introduced, as they answer the same end, but in a less degree; they serve as a shade when the object is in shadow. In all cases where this uniformity of surface and equally diffused light is supportable, shadow, or what is equivalent to it, will be somewhere found to have occasioned it, either by gloomy trees or other dark objects connected with the view. Canaletto would make good pictures of our worst churches by employing his skill in the relative picturesque accompaniments.

Defects of the Pantheon, Rome.

The edifice has faults, and great ones, circumstances which are certainly injurious to its perfection and to the agreeable impression on the mind of the spectator. The columns are rather too small in proportion to the size of the building; the entablature is disagreeably interrupted by two arches, and these arches on a curved surface are necessarily supine, that is, the crown falls back behind the springing, and this gives them an awkward appearance. The space above the columns, which is a modern alteration so late as the last century, is altogether bad. Till then an attic existed adorned with pilasters, formed not in relief, but by different coloured marbles. This was attributed to Septimius Severus, and not generally approved, but it seems to have been well calculated to preserve the general impression of the building, and to have contributed to give rather an increased value to the order below. It would probably be better (internally) to make the upright part of a building of this sort somewhat greater than the semidiameter of the circle on the plan; at least in the present case, the dome itself seems to come rather too near the eye and to occupy too much of the view, especially in the condition it now is, presenting an overwhelming extent of whitewash. It is supposed that this was also covered with bronze panels, but the time of their removal seems uncertain. These panels would probably have followed the disposition of those now existing in the brickwork and stucco; that is, they must have been in square coffers, and in such a case the most obvious way of cutting the recesses is to make them at right angles to the surface of each part, or, to speak more mathematically, at right angles to the tangents of the surface, and consequently all tending to the centre of the curve; here they are cut in almost vertically, or if they do tend to a common centre, it is to one below the eye of the spectator standing in the centre of the room. Some people affect to understand the reason of this; but the result is distortion, and if really intended to produce any pleasing optical deception, it must be attributed to great want of judgment, as it could only succeed from one spot, and must look ill everywhere else; whereas, without any such contrivance, the spectator himself would at once make allowance for situation, and the mind would be satisfied; for in architecture, and probably in all the fine arts, it is often rather what we understand than what we see that produces the sensation of pleasure. In unusual situations some allowance may be permitted, but it should always be so limited that a moderately practised eye will not perceive it. If instead of being drawn to the centre of the hemisphere,

which is the most obvious method of forming them, the lines of the recesses had been directed to a point 18 or 20 feet below it, it is possible that they would have appeared to tend more correctly to that centre than if they had been really drawn to it; but as they are, everybody at once perceives that they are not so drawn. These panels are omitted for a circle of considerable width round the opening in the centre, but we cannot doubt that this part also had originally its share of decoration. The little altars are all bad in design and worse in execution, but not all equally so; the best of them are usually attributed to Septimius Severus.

Reverence for Antiquity.

The reverence for antiquity is to be no blind passion, as some suppose it to be. Is it not a respect for the productions of thinking reasoning minds—of great men who, having certain requirements to fulfil, pursued a train of laborious thought, studied nature herself for sources of inspiration, and felt that they had to realise the wants of well-informed and highly-gifted men? It was no wild caprice or loose imagining which planned the Parthenon and designed the Colosseum or Pantheon. It was a grave people who conceived and executed the overwhelming and awful edifices within the sacred precinct of Karnak and Luxor. Were not these independent minds? Were these servile imitators? But did they create these at once from their own resources or, as the phrase now is, "from common sense," a term identical with presumptuous ignorance? These great men studied the productions of previous periods, well weighed all their own wants, and hence resulted works that have commanded the respect of every succeeding age. In fact, without a knowledge of the Classic monuments of antiquity no one can have other than an imperfect, faint image of architecture. Egypt and Greece had an existence peculiar to themselves. Independently of intrinsic beauty, their art had the great taste of perfection, unity, simplicity, appropriateness. In studying the fine productions of the Greek and Egyptian minds we do not acquire merely the proportions of a cap, a cornice or a column, but we intuitively impress our minds with noble and sublime principles, and by the contemplation of simple and grand edifices receive impressions which are imperishable.

Architect's Sketches.

It is not enough that the edifices of Greece and Rome have been correctly published by others. If the student wishes to know a building thoroughly he must measure it himself. And the greater the number he measures, the vaster will be his store of useful authorities and types to assist his invention and to guide his taste. But to increase this store to a greater degree, and thus gain an inexhaustible fund to which he may refer on any occasion, it is desirable that the architect, at whatever stage it may be of his practice, should carry constantly with him a sketch-book. He should make a slight drawing of anything which may strike him as remarkable and worth remembering. His motto should be, "Nulla dies sine linea." The very act of sketching an object will impress it upon his memory. But in addition to that result he will have a more exact notion of it, and if he should forget it he has it upon record for future reference, and certainly he will thus acquire the habit of more exact observation. The sketches should be subsequently arranged systematically in a larger blank book with a proper classification of subjects, and by this means he may ultimately possess a most interesting series of precedents, descriptions and authorities, whether in art or in the sciences connected with architecture. He will thus have a collection which will readily furnish ideas, that will appear to rise spontaneously, but which in fact will only be the fruit of these seeds which he will as a student have so laboriously collected in his earlier years.

Study of Buildings.

Many students in architecture seem to employ themselves wholly in measuring different buildings, ancient or modern, and imagine that while so doing their time is necessarily well employed. To a certain degree this is a desirable occupation, and it fills the portfolio and makes a great display of industry; yet it is possible to be more industrious, and more usefully so and have less to show. No artist has the notion of ever following any of these buildings minutely in his own productions. Who would ever think of copying the Pantheon in its precise dimensions and in its details, or what employer, either public or private, could ever require it? and if it were done, have we not engravings which would be sufficiently exact? In a length of 144 feet it is impossible to consider an inch or two more or less as of any importance. Nor is the wish to return with a great number of laborious drawings a reasonable motive. After the first month or two they are neglected, and as they have little beauty in themselves and are not wanted for imitation, they sleep perhaps for ever in the portfolio. The real motive for measuring any building is to understand it better. The student's attention is forced in succession on each individual

part; he gets it, as it were, by heart, and what he possesses on paper is of little value compared with that which he fixes in his mind, and indeed the principal merit of the first is that it recalls the latter, which among so many objects might be forgotten. What the student has to do, then, is to see every ancient building and every modern building of consequence; to remark whatever pleases him and to note it on paper, either in writing or by sketches, or rather by both; to consider what are the circumstances to which the effect which he admires is owing, whether in the general distribution of the masses, in the disposition of the orders or in the minuter details, and to take such dimensions and make such drawings as would enable him upon occasion to produce a similar effect, and this mental process is to be applied not merely to the beauty, but also to the solidity, convenience and economy of the edifice. This will form his principal employment, but besides this he will find it advantageous to notice whatever either in plan or in ornament gives character to one edifice or to one style of architecture; to copy in detail a few of the most beautiful ornaments, whether of friezes or of capitals, or of any other part, and to go completely through in plans, sections, &c., one or two ancient and one or two modern buildings till he makes himself quite master of the feeling of the artist.

Etching.

M. Lalaune says, "L'eau forte doit être vierge comme une improvisation." It is exactly this freshness, this "virginity," that is wanting in common etchings. No ordinary artist can work in this brilliant and rapid way any more than a common speaker can make, without hesitation, a speech perfect enough to bear cool criticism after it is reported. Then, again, this faculty of doing right at once is a special gift; we know good artists who are naturally destitute of it, men who have to seek painfully every separate quality in their pictures, and who, nevertheless, by dint of long seeking and correcting paint valuable works in the end. Still these men, however great their information and even power as artists, are not so constituted as to succeed in etching, because their information is not fully available on the spur of the moment, nor their power combined with that decision and agility which, in etching, are necessary to its effectual display.

S. Francesco della Vigna, Venice.

The plan of the church of San Francesco della Vigna was prepared by Sansovino. A representation of the façade is given on a medal struck in 1534, but the Patriarch of Aquileia, at whose expense it was to be built, not thinking it sufficiently magnificent, employed Palladio, in 1562, to make the design which was afterwards executed. It appears that Sansovino's plan (already begun) was, in 1533, submitted to Francesco Georgi, a brother of the convent, who proposed to rectify the proportions according to what he called Platonic principles. "I would," said he, "that the width should be of nine paces, nine being the square of three, a prime and a divine number; and that it should have a triple proportion to the length, which should be of twenty-seven paces, forming a diapason and a diapente;" and then he goes on to say that this relation and harmony was appointed by God himself, who thus fashioned the world, and directed Moses to observe it in the tabernacle, which was to be made according to the model shown to him on the mountain; which model, according to the opinion of the wise, was the world itself. The author proceeds through all the parts of the church in the same style. That men should have such dreams, that they should write them, may not be a wonder, but that they should think such dreaming to be reason, that they should publish them as such, and that the world should ever have received them as such, does seem to be a little marvellous. With all these harmonious proportions, however, or without them the inside is not beautiful; the outside does not at all correspond with it, and nobody need doubt that the building was the work of two architects. Palladio's churches have all one general disposition in front—a pediment in the centre supported on half columns and a sloping roof on each side, resting on a smaller order, whose horizontal cornice is continued more or less perfectly in the intervals between the larger columns. The effect is always in some degree as if a great pediment over the smaller order had been cut away for the purpose of introducing the larger; and on this account it would be better entirely to omit all trace of the smaller order in the intervals of the larger. However, though not absolutely perfect these buildings are very graceful, and hitherto no better mode seems to have been adopted for accommodating Roman architecture to the usual disposition of a Christian church. In the present example the lower cornice is only continued in two or three flat members in the inter-columns, and there is a small projection in the wings on which the cornice returns, so that these flat mouldings alone are interrupted by the columns. Both orders are on a high continued pedestal which breaks round the principal columns and is cut through to admit the door. Over the door is a large semicircular window.

NOTES AND COMMENTS.

ALL over the world Government departments appear to be inspired by one principle, which is that the ease and security of the officials must be paramount to public needs. The United States at the present time are affording an apt illustration of the application of the principle. The public buildings throughout the country are not worthy of a people whose progress is without precedent. Only one remedy can be discovered, which is to restrain the inventive power of the Governmental department of architecture. It was supposed when an Act was passed authorising the employment of unofficial architects that the improvement was about to take place. But Mr. CARLISLE, the Minister who fills the office of Secretary to the Treasury, grew alarmed at the consequences of the power that was entrusted to his discretion. Instead of arranging for a competition for public buildings in Buffalo, he followed the old jog-trot course which has led to so many failures. There was an outcry, and officialdom declared that the language of the aggrieved architects was so unlike the prescribed forms for use when addressing important people that, without loss of dignity, there could be no reply. It was an ingenious way of evading a controversy where law and logic were on one side. Mr. CARLISLE now frankly explains that if he has allowed the Act to remain inoperative it is out of respect for official rights. He announces that "the required change in the method of preparing the plans, drawings and specifications would necessitate a reorganisation of the office of the Supervising Architect, a reduction in its force, the rearrangement of the different divisions and the work to be performed therein." We suppose there never was a new law created which did not require some sort of shuffling of people, but, as political economists say, men are free to transfer themselves from one occupation to another. The American Legislature must have contemplated changes when the TARSNEY Bill became law, but an improvement in buildings was worth a little sacrifice. Owing to the terror of Mr. Secretary CARLISLE the people must be content with whatever ugliness the official imagination can devise, and economy must be ignored because the obtaining of designs from competent hands would necessitate a reduction of force. The Secretary proposes an amendment of the Act which would allow of the appointment of commissions, bargaining with architects, valuing of the services rendered, and, above all, would impart authority to the Secretary to preserve the old monopoly of the Supervising Architect's office, all of which means that it has been decided to leave no effort untried to prevent architects from having any share in the designing of the public buildings of the States.

A DECISION has been given in the Edinburgh Dean of Guild Court which must affect building operations in that city. There, as elsewhere, people desire to have higher houses than were formerly erected. Accordingly, when application was lately made for approval of plans of five-storey dwelling-houses at Montpelier, the owners of property in the neighbourhood, whose houses would appear of diminished importance, as they were of inferior height, lodged protests. The ground of objection was that the proposed houses would infringe the provisions of the Edinburgh Municipal and Police Act, 1891, and the Edinburgh Improvement Act, 1893, since their height exceeded by 8 feet 3 inches the limit permitted by those Acts. The applicant contended that the provisions of the statutes regulating the height of buildings referred to either (1) existing houses which were to be increased in height, or (2) to buildings in entirely new streets to be formed and laid out after the passing of the Act. He also pleaded that he was neither increasing the height of old houses nor building houses in new streets. It was maintained that the terms "height of houses or buildings" did not bear the construction put upon them by the objectors, as the height was to be measured to the ceiling of the highest room. After giving sufficient consideration to the points raised, the Dean of Guild Court decided that the plans, if carried out, would be a contravention of the Acts. It was also laid down that the provisions applied to new as well as to existing houses, and that the words "height of houses or buildings" meant the

height measured, not to the ceiling of the highest room, but to the ridge of the roof. The applicant thereupon agreed to reduce the houses to four storeys, and in the amended form the plans were approved.

THE sale of 3,446 prints during last year by the Art for Schools Association is a creditable achievement. It is further evidence of the necessity to make classrooms pleasant to the eyes of children. Nor can it be said that the introduction of pictures causes a neglect of studies. At the annual meeting of the Association which was held last week a letter was read from Mr. ACLAND, M.P., in which he said:—"To brighten the walls of our schools and to add to the happiness of the children by showing them beautiful and artistic objects is a most valuable service rendered by you. I much wish that a series of designs on a large scale, not less than 6 feet in depth, for the upper part of the walls of schoolrooms could be brought out. You are aware that I have promised to assist the visits of children, under proper conditions, to art galleries and museums." In his interview with a deputation a few days before Mr. ACLAND spoke as if he referred to painted friezes. From his later utterance it would appear as if he thought printed friezes would serve. It is needless to say there is a great difference between the two classes of work. To produce a printed frieze 6 feet deep is not a speculation that many publishers would care to undertake. The nearest approach to it is a coloured "theatrical poster," which is made up of several sheets. The posters are not made to endure, and a large frieze on paper would soon look shabby, although it might be protected by a coating of varnish. Prints that can be covered with glass form the best decoration for a schoolroom, and they are the cheapest. In the numerous Board and other schools where plates from *The Architect* are employed, there has been no more objection to the scale than to the subjects. If pictorial works on a large scale are to be employed, it would be wiser to imitate the Parisian plan in the few cases where they were tried, that is, not to place the paintings high up on walls, but on a level where children can scrutinise them and make drawings from them.

THE case COWELL v. ELKINGTON, which was tried before Mr. Justice GRANTHAM on Monday, will be considered to support those critics who say that fine bronze work, especially of the medallion class, cannot be satisfactorily produced in this country. That there is little practice in medallions is true, and without practice perfection is not to be reached in metal-working. At the same time, it is undeniable that the defendant firm have produced excellent work, while failures are not unknown among the chief bronzists and electrotypists of Paris and Berlin. The failure which gave rise to the lawsuit would appear to be due in some measure to want of experience. The plaintiff, Mr. COWELL, a sculptor, modelled a head of TENNYSON as a medallion. He was eager to have copies produced at Christmas time, as he expected to sell them at from three to five guineas apiece. He agreed with the defendants to supply electrotypes at half a guinea each. Mr. COWELL furnished a medallion in wax, which is generally supposed to produce the sharpest reproductions. Only six copies were taken from it, and as they were not considered satisfactory Mr. COWELL declined to allow their sale. The original was also damaged by distortion. The action was taken to recover damages for injury to the wax medallion and for loss caused by the delay in carrying out the agreement, for the remainder had to be electrotyped from a plaster medallion. The defendants' case was that the wax medallion was too thin, as it was not backed with plaster, that their manager informed the plaintiff of the fact and that proper skill and care had been used in the process. The jury, by direction of the judge, confined their attention to one point and gave a verdict for 175% for the injury to the wax model. It was considered as a work of art, but for the future electrotypists and all foundries are likely to decline reproductions unless the owners of the original models will agree to accept all risks. It is well known there are medallions in wax which up to the present have not been reproduced through apprehension of injury to them.

SOLICITORS TO THE SUPREME COURT LIBRARY, EDINBURGH.—
END OF LIBRARY.

NEW ENTRANCE LODGE, DINORBEN COURT, HANTS.

THE entrance lodge which forms one of our illustrations to-day has been recently erected at Dinorben Court, Hants. The work has been satisfactorily carried out by Messrs. J. POOL & SON, builders, under the supervision of Messrs. CHARLES SMITH & SON, architects, Reading.

AN INGLE NOOK.

THE sketch which we publish to-day shows an extension of a living-room in an architect's small suburban house. The length of the room has been increased 5 feet by pulling out the old chimney-breast and inserting an iron girder to carry the breast of room over. The additional space thus obtained is fitted up in oak with book-shelves, cupboards, &c., and forms a comfortable and interesting feature in the room. Messrs. COLLIER & CATLEY, of Reading, were the builders.

PROPOSED HOUSE AT HORSELL.

THIS house is to be built on the hill overlooking the church and village of Horsell. It is so arranged that every living-room and all principal bedrooms face south. The walls are to be faced with Chobham bricks and the roof covered with local-made tiles. Simplicity of plan and style are necessary, as the accommodation shown is provided for 1,800 $\frac{1}{2}$. The architect is Mr. J. HENRY BALL, of 15 Clement's Inn, W.C.

DETACHED RESIDENCE AT SURBITON.

THIS villa, now nearing completion, has been erected facing and in St. Andrew's Square. The nature of the site necessitated cellars under the greater part of the building. The front and sides are in red brick and red tile hanging, the front gable overhanging 18 inches, and having rough-cast, &c.; the roofs also are tiled. Clear lead glazing has been introduced in the windows, and the ceilings of the reception-rooms and hall are panelled. The work has been carried out by Mr. E. H. BETTESWORTH, who has been acting as manager for, and under the superintendence of, the architect-owner, Mr. R. LANO PEARCE, M.S.A., of 100c Queen Victoria Street, E.C., and Surbiton Hill.

THE PRACTICAL SIDE OF TRAVELLING.*

(Concluded from last week.)

THE permissi are a modern invention, a plague of officialism on the field of art, and an ill-considered method of compensating, by State action, for the personal care of the owners, now dispossessed, of their churches. The most justifiable and useful permesso is the free pass at Pompeii, given at the Naples Museum to all who are students, and which frees you from guides and the entrance fees rightly enforced on tourists. Next comes the one to be obtained at Florence, which also gives you the right of a free entry to certain museums and old buildings, but which, like many others, does not confer that freedom of action as to measuring and architects' work which can best be obtained, as a rule, where the priests and monks are still in possession.

At Rome there are no less than three authorities: first, the royal Government, in the Via Ripetta, to obtain a permesso from whom a letter from your consul is necessary, stating that you are an artist, the Royal Institute of British Architects' card not being considered sufficient; secondly, the municipal authority, who have control of the Capital Museum, containing some fragments of architectural detail; and, lastly, the papal authority, for the Vatican Palace and Museum, who must be applied to a few days in advance, and whose form does not include leave to measure. The Vatican is the most expensive building in the world, I fancy, to see over, as at each door a guardian expects something. Go, therefore, provided with plenty of copper. It is also of little use to apply to see parts of interest to an architect which are not shown to the public, unless you can command influence with the authorities. In other places, as a rule, do not apply at all for permission, as it wastes so

much time. In churches and convents observance of the hours of opening and shutting, and taking care not to be in the way of services, will generally suffice to prevent your being interfered with, and will, where there are no officials in charge, as a rule, suffice, as the priests and monks are generally well disposed to artists, and they will often lend assistance in a way that no official would dream of doing. As to working in churches, you need not be afraid to work if a service is going on, provided you are not in the way or in too conspicuous a position, and provided also that during mass or benediction you pay some attention to the bells, so as to cease from working at moments when reverence is required. If, however, it is a feast day, or the church is a specially fervent one, this will not apply, and you will, of course, stop at once on being asked to do so, which will create a good impression and facilitate your work another day. Continental ideas of the use of a church are, as you will soon find out, different from our own; there is more of the public place, museum and temple than of the meeting-place, to be occupied only for so many hours a day or week. Very likely you will prefer your own ideas, but need not any the less observe these while there. I cannot see that difference of opinions can be justifiably translated into outward conduct in foreign churches, especially at service time, and nothing more is expected of any one than an inoffensive neutrality of attitude, especially necessary when the chief places are taken by our ardent sightseers intent on putting through a function. If a cantankerous sacristan should refuse permission to draw and refer you to authorities, it is not always well to hunt them up, because of the loss of time, difficulty of finding them, of making yourself understood, and of working in face of opposition when leave has been obtained. If the sacristan cannot be overcome by persuasion or a bribe, it may be wisest to go on to another place. In Spain, however, the priests seem to have a greater control over their minor officials, and I have found them most favourably disposed to students, regarding leave to draw as a matter of course, which is our view of the question. I often pity the poor foreign student who comes, if he ever does, to England to work, where the making of drawings seems to be considered as a deduction from the value of the property, and a consequent offence, and where many parsons expect to be humbly sued by the poor artist for their ungracious leave to ply his trade.

As to the sight-seeing of show-places, it is of course absurd to spend time in seeing what you do not like, but until you have seen it you cannot know what it is like, excepting by analogy, *i.e.* from having seen similar places, and then you will be very likely less inclined to omit the regulation visit, perceiving that there is some advantage in having seen what the average man sees, and what he will talk about if the subject should be discussed. It is a saying of Goethe's that you will only find in Rome what you take there. Many places owe their attraction to associations, historical and literary, and the charm is absent unless one has some previous acquaintance with them. On the other hand, seeing such places is a powerful motive to reading, giving some actuality to the dry pages of history. Advising students what to see is risky, because they may miss the point of interest for which the particular building is valuable, and may then fall foul of your judgment, as in the case of old buildings, now encased in bad detail, which are only to be realised by the skilled observer.

As to the time to spend in travelling there are two plans—the rush round and the long tour—which both have their uses and are better not mixed. A rush round should be short, say three weeks, and should cover all the important places in the country, so as to gather a general impression of its art, and an idea of what class of work you will take up when you come back again, and it is better to attempt no work at all. I am all in favour of the long tour; the rush round I regard as a useful preliminary, and certainly better than none at all, but a country cannot be studied, as it is, without a residence of some length, and without the exploration of its smaller towns. A brief tour gives one a better knowledge, in one's own opinion, of the country than a longer, when one will feel that one knows nothing, so many are the aspects and causes, that that can be dimly seen beneath the surface. When I made my first rush round Italy it was spring time. Florence was all wind and Venice all rain. The lilac only was out and fields were bare. Where, I wondered at the conclusion, was the Italy of poet and of painter? and I resolved that next time I would go through the summer and autumn in the country. This I regard of great importance. A hot country must be seen in the hot season to understand it, and to appreciate it at other seasons also. Heat can always be supported by observing the customs of the people, which are the results of centuries of experience. From an architectural point of view the long tour is even more desirable, because important things can be undertaken which would not be worth doing in a hurry, and in our work the details have often a great influence on the scheme. Moreover, towns and villages that are not worth visiting, in a rapid review, are worth seeing when time is less of an object, and then we can see what a style means in its

* A paper read by Mr. Bolton at the last meeting of the Architectural Association.

smallest work and often how it originated. Previous to over-running a town consider its history, for towns grow like trees, in successive layers, and street improvements are not a modern invention. Thus, at Rome, the work of Julius along the Tiber contains interesting work of the architects of his age, no other than Raphael and Bramante. Avoid suburbs and outskirts of towns, except where you have reason to expect that churches, once in the fields, have been engulfed in them. Sight-seeing is fatiguing and over-walking should be avoided. The long streets of Paris are a great snare to enthusiasts who fail to realise the distances. On a long tour, when visiting a town, it is best to devote the first day to going round, and it is a good plan to do this with your companion, as there is economy in sharing the fees, and it is generally advisable to make the regulation visit round the chief buildings, and often to ascend the towers or the roofs, both for the sake of the curiosities of their construction and to get an idea of the city as a whole. When doing this first day's visit you should note down what appeals to you most, forming a programme of work which you may, or may not, be able to complete before you have to go on. You can also thus best arrange with your friend as to the duration of your stay by each alternately making concessions.

Sight-seeing is education but not study; sketching is practice in perspective. It is in measuring-up that the special work of an architect consists. That would seem to be most useful as study that most closely resembles your daily work. Work therefore on your usual papers, with usual pens, pencils and colours. One would say that you will best provide against disappointment if you represent your new work in a similar style to that in which you have drawn the old. And it has often been said before that while a painter's picture is his finished result, that of the architect is only a means to an end, the building being the product by which he is judged. I confess to a fancy, however, that there is a value in a rough style of drawing for effects which would shock the conservative, assuming that it is merely supplementary to sound elevation, plan and sectional drawings. In the result, much of architecture is due to the sun, and the value of a photograph is often that of its light and shade. I do not desire, however, to enlarge on this topic, for precept is one thing and what is successful is another, and I could only expect you not to blame me in the result if you had been following your own bent, which is the best advice that anyone could give. The pursuit of a method to its logical end is the truth or reason of many men's achievements.

Sketching is supposed to be a matter of instinct; hints are generally more wanted as to materials than as to methods. In measuring, however, there are certain difficulties which one may fairly expect to have explained. There are practically two ways of drawing buildings to scale, the first the old "measured sketch," which is a ruled elevation to scale set up from measurement of the lower accessible portion of the building, what is not to be got at being put in by proportion to what is known. The other method, the measured work proper, is drawn out, not necessarily on the building, from sketches of every feature, with its measurements attached, the drawings being as it were built up from the various details of the building. The best way to go about the latter method is to rule a diagram of the front on a block of say $\frac{1}{4}$ imperial size, on which your main dimensions will be put, and then to sketch all the various features on sheets of the same size, so that you can keep them all pinned together for reference. Good measuring could be drawn out by anyone, a standard of perfection I do not claim to have reached myself. The greatest difficulty is to get the key dimensions without unnecessary measurements, which serve only to obscure and confuse your work. As to ladders and scaffolding, they cannot generally be obtained, and ingenuity has to supply their place. Much can be done by measuring from above, from the parapet or cornices from one level to another and from window to window sideways, and up and down from a window to strings, and so down to the ground. In one drawing exhibited the problem was to obtain the total height of a building which was a mere shell without any upper floors, the façade being a smooth stone wall, the top of which was inaccessible. Eventually it was done by slinging a plummet at the end of a string right over the top, and drawing up the tape then attached to it until it touched the underside of the top fillet of the cornice. The total height was thus obtained, as well as the projection of the cornice, the height to its underside being ascertained by means of an unfinished cross wall, the top of which was nearly level with some circular attic windows. To get on to this cross wall a rustic ladder of insignificant height was only available, but there happened to be a fireplace in the wall, and as the ladder could be safely stood upright in the recess, and as it is easy to pull yourself up out of a hole if you can get a hand on its rim, the flue proved a possible method of ascent. Thus the attic windows were measured, the height of architrave and frieze and various other details obtained. Spires and tall roofs can be obtained by some methods given in the "Architectural

Drawing-book," but the best way is to climb up inside, as there are generally pieces of wood nailed on to the central posts in the case of timberwork.

I admire, myself, those who do not omit the difficult and tedious work of projecting the corbels of a cornice on a circular part, or the correct setting up of tracery, or those other points of drawing which appeal only to the skilled observer. Arches and vaulting are also not so difficult to measure as they appear, and you should copy out of Spiers' work the methods of doing them, to take with you until you are efficient in them.

It appears to me that there are things which are worth measuring in a diagram style, for the sake of the proportion and outline rather than of the detail, and in these cases it is surprising how quickly by practice such examples can be measured so as to be drawn to one thirty-second or one-sixteenth scales. You will need only the key dimensions, one pillar or pier for the plan, and the general heights only for the section or elevation, and can put in the detail of the style as you like, but such work should of course be distinguished as a measured sketch. Measured work is so laborious that it is not surprising that cheaper methods are common, but the putting of dimensions on to a sketch is not, to my mind, of the value usually ascribed to it; the proportions are not to be obtained thus, and as a rule such dimensions are inadequate if you try and draw out the work, while the possession of old work to the scales you are accustomed to is of great value. What architects differ most in is the number of features that can be crammed into a façade of a given length, and how can scale be learnt save by experience of old work?

In conclusion, the advantages of travel are questioned mostly by those who have not been abroad, and a chance of going modifies much our views of the subject. Anyone will admit of course that why the advantage is often little or none is due to the spirit in which it is undertaken. No one can be taught against his will, and an atmosphere of prejudice will prevent any man learning the most obvious facts. The value of going more than once lies in the fact that the first impressions are most distracting, and I think that a rush round, which gives some general idea of what there is, has a great value as a prelude to a second more serious working tour. And I think this first rush round of the beginner should be taken much earlier—in the pupil stage or, better still, before, as nothing should so open the eyes of the beginner as to what architecture means as a sight of the grand buildings of the past; moreover, time is not lost in this wearing off of the novelty of fresh impressions, as on a second tour work can be better done, the mind being less distracted.

From other points of view it must be remembered that we live on an island, and by imports in art as well as in food, and this importation has been continuous. Hence old work, no less than modern, is best understood when foreign originals have been seen. Canterbury choir is not less liked when you have been at Sens, nor the Reform Club when you have seen the Farnese, and only the other day I was interested in seeing Spanish features in St. Mary's and the cathedral at Bristol. Architecture is wider than nationality, which shows itself mainly in the class of building chiefly required, being better treated in one country than another, and in a certain general stamp of the characteristics of each race, such as refinement, grandeur, vigour, &c., in less or greater quantities.

The greatest abuse of travel is heedless importation of features that have no previous root here, instead of learning how to modify the old for the work of the present. Imported work usually dies out, however fashionable it may be for a time, and a design should not require to be understood by the light of what has been done exclusively elsewhere.

That there is nothing more to learn, owing to the numbers who have been there before you, is a pure delusion. It is extraordinary how the obvious is overlooked. Hundreds had seen the Town Hall at Piacenza, but when brickwork was built on granite with no division between, it was justly regarded as a novelty; and, as Bacon says somewhere, chance is more responsible than pursuit for most of our discoveries, what is known being but a particle of what is passed over.

The importance of travelling may easily be exaggerated, but as nowadays the world in general travels, the architect at least should have seen the more important monuments, as his client will very likely have had that advantage.

From the point of view of examinations I would prefer to spend the fees of all the courses in seeing, rather than hearing, about the buildings and architecture in question. If you have been at Vicenza, Palladio will never stump you, and Scamozzi, Ictinus and others, when you have seen their works, will be no burden on your memory.

The greatest, however, of all the advantages of travel is the acquirement of freedom. Every generation has in art, as in other matters, its own cant ideas and phrases. Travel is emancipation in that art is wider than convention, and a knowledge of all the styles of the past is the best protection against the formulas of the day. When told of such and such mysterious qualities to aim at and this or that method of doing it, you can

reply effectually by quoting some leading building treated on the reverse method; and if that be excluded there will always be another, for art is wide and principles are hard to stretch. As has been said, the subtlety of nature is beyond understanding, so that the theories of mankind are a kind of insanity, only there is no one to stand by and observe it.

Bygones.

"Antiquity after a time has the grace of novelty."—HAZLITT.

RICKMAN'S LETTERS ON THE ARCHITECTURE OF FRANCE AND ENGLAND.

(Concluded from page 357.)

LETTER V (continued).

8. THE EAST END OF WHITTERING CHURCH, NORTHAMPTONSHIRE,

has some portions of long and short work, and the arch between the nave and chancel is built of large rude blocks of stone with very little attempt at ornament.

This church has a short tower and low spire, and has nothing attractive in the view from the great road, from which it is distant only a few hundred yards, being on the road from Stamford to London, and is nearly, if not actually, the next parish to Barnack. The church is well deserving of attention more than it has received, and is a curiously connecting link between Barnack and Earl's Barton.

9. BRIGSTOCK CHURCH

is another curious specimen, but here the early work forms only a very small portion, though surrounded by ancient remains of such a character as to confirm, as much as their antiquity can do, the earlier date of this portion. The tower is of very rough masonry, plastered, and has a roughly built round staircase on the west side, as at Brixworth. The tower opens into the north aisle by a semicircular-headed small plain door, with a small window over it. The arch into the nave has large plain blocks for impost, and a projecting stone round the arch, like those at Barton-on-the-Humber. The pier of this arch is on the north-east corner of the tower, abutted against by Norman piers and plain arches; the rest of the church has various interesting features of several styles, but nothing more appears now to remain of a character like the lower part of the tower, which has above it a belfry and spire of a date somewhat later than that at Brixworth. There are several good doors and windows, a small water drain, a beautiful niche in the chancel and the stairs to the rood-loft remain.

10. BRIKWORTH CHURCH.

This curious church had not, to my knowledge, been noticed till visited by me in company with my friend G. Baker, the historian of Northamptonshire, near the end of the year 1823, which visit led to a subsequent more minute examination of the building, and a search for traces of the parts which have been destroyed.

This church, in its original state, appears to have consisted of a spacious nave and narrow aisles, a large chancel and a western tower, with a clerestory to the nave, and the chancel divided from it by a large arch. The lower storey of the tower had four doors, one on each side of the north and south, small; the east and west large and lofty. In the upper part of the tower, and looking into the nave, is a window, with two of the rude balusters found in the windows of the tower of the old church at Barton-on-the-Humber. In this state the church would be near 120 feet long, the nave 30 feet wide, and the aisles appear to have been from 10 to 12 feet wide; but as the foundations, which were discovered by digging on the north side, were irregular, this width is in some degree conjectural, although it is not likely to be more than a foot or two wrong. If we suppose 11 feet as the medium for the breadth of the aisles, it will give the exterior breadth of the church, in its original state, 66 feet, as the walls are near $3\frac{1}{2}$ feet thick.

The construction of this church comes now to be noticed, and this is particularly curious, the walls being mostly built with rough red-stone rag, in pieces not much larger than the common brick, and all the arches turned, and most of them covered with courses of bricks or tiles, as they may be called, precisely similar in quality and size to those found in Roman works discovered in this country, and over the balusters of the window looking from the tower into the nave, these bricks are used as impost.

The great arch, between the nave and chancel, has, at an early period, been partly taken down and filled up with a good

pointed arch; but this was not so completely done as to destroy the remains of the spring of the original arch, which, on stripping the plaster, was found to have the same tile impost and tile arch and course of covering tiles as are found in the other arches. At what date the church remained in its original state I do not presume to determine, but from the nature of the alterations now extant it must have been very early, and I now proceed to state these as they appear.

The north door of the tower is stopped up, and against the west side of the tower is erected a circular staircase, built of the rag stone in a very rough state; the stairs are partly remaining, and the under side of them has been formed upon rough plastered centering, in the mode usually adopted by the Normans. To afford access to this staircase the original west door of the tower has been partially stopped, and the aperture is a small circular-headed door. There is no other access to these stairs, and they lead to the two storeys of the tower, reaching rather higher than the present remains of the original steeple, upon which is now a belfry and lofty spire, of a style which may be considered of from 1300 to 1330.

Proceeding eastward, we find the original aisles destroyed, and the westernmost arch on the south side remaining to its original use, but now leading into a south aisle, nearly of the date of the belfry, and to give access to the eastern part of this aisle the wall of the original chancel on the south side has been opened and two arches inserted, which are dissimilar in their shape, range and mouldings. In the arch next the tower on the south side is also inserted a door, and of such a character as to fix its date to about the year 1150; it is covered by a porch of a date somewhat later. We now come to the present chancel, which is an addition eastward of the original one. The east end had originally one large window and two small ones; the lower part of the large one has been opened to the ground, widened, and the upper part supported by a wood lintel resting on two wooden uprights, against which are some remains of a Perpendicular wood screen. Eastward, the present chancel consists of portions of each of the four styles; on the north side, joining the old chancel, are parts of two Norman divisions with small flat buttresses, and such a direction as to make it probable that this Norman chancel was multangular eastward. In these two divisions are inserted two windows, one a Decorated two-light window, forming a north low-side window, the other a Perpendicular two-light, which is so inserted as to preserve above it the Norman arch of the window originally lighting that division. The rest of the chancel below the string is Early English, and has Perpendicular windows above; on the south side is a Perpendicular door and a low-side window of the same date. The nave is now lighted by six windows inserted in the old walls, all of different sizes, and, with the exception of two, which are alike, of different dates. A vestry has been formed in the nave, opposite the porch, and a wall built across the nave at that part, forming a screen; the vestry is lighted by a small window, differing from any of the others.

This church has been thus particularly described on account of the extraordinary preservation of so much of the original structure, amidst alterations which appear to have been carried on from the time of the Normans to the Reformation about every fifty years, for so diversified are the different additions and insertions as to character; it is also curious for the discovery of a relic in a small shrine, which appears of the age of the south aisle, and was inserted in the south wall near a window. Interfering with a seat, it was taken out of the wall, and behind it a cavity was found containing a small wooden box in which was a small bone, which, with the shrine, is carefully preserved.

11. EARL'S BARTON, IN NORTHAMPTONSHIRE.

This tower, which, as well as that of Barton-on-the-Humber, has been engraved in Britton's "Architectural Antiquities," is apparently of the same character, but more ornamented, and with rather more finish of workmanship; it is, however, still rude compared with most Norman work, and its west door has a curious approximation to Roman work in an impost with flutes, and a rude moulding over it, similar to a Roman architrave. The baluster is used to the windows; the number of stone ribs is greater than at Barton-on-the-Humber, and the upper storeys of the tower diminish in size a few inches each way, less than the storey below. This tower so clearly resembles Brixworth in the baluster, Brigstock in the work about the door and Barton-on-the-Humber in general character, that there can be little hesitation in considering them of the same class, and the tower of Barnack before described assimilates also in several points to Brigstock and Earl's Barton. The church of Earl's Barton is highly interesting, exclusive of its curious tower. The chancel below the window, the south door of the church and some other portions are Norman, good and much enriched; other portions, both of church and chancel, are Early English, and the north door and some of the windows are Decorated, while some inserted windows and the clerestory are Perpendicular. There are two Early English water-drains and

three Norman stalls. There have been low-side windows to the chancel, but they are now stopped. The arch from the tower into the nave is evidently an insertion of later date than the rest of the tower; it is partly Norman to the spring of the arch, and Early English above.

12. THE TOWER OF CLAPHAM CHURCH, BEDFORDSHIRE.

This tower is wholly plastered and rough-cast outside, and therefore does not show the long and short work; but a very attentive examination of the interior of the tower, the construction of the windows, the absence of a staircase, the great thickness of the walls, the material used (small rag stone) and the general appearance induce me to include it in this list of early churches. This church is very near the great road about two miles north of Bedford.

13. THE TOWER OF THE CHURCH OF ST. BENET, IN CAMBRIDGE.

The long and short portions have been here obscured by plaster and rough-cast; but during the sitting of the British Association at Cambridge in the year 1833, I had permission of Dr. Lamb, master of Corpus Christi College, to remove so much plaster as should settle the construction of the tower, which was done, and the long and short masonry clearly developed. The arch from the tower into the church (a large semicircular one) resembles the arch at the west end of Kirkdale Church in a degree of approach to Norman, and the impost and arch mouldings assimilate it to Barnack and Earl's Barton, while certain rude animals, in the place of a drip supporter, add another curious feature. This tower is not sufficiently known, being a good specimen and in excellent preservation; it has the baluster belfry window and no staircase. The west door and window over it are insertions.

14. THE TOWER OF THE CHURCH OF ST. MICHAEL, IN OXFORD.

This tower, like Clapham, in Bedfordshire, was till very lately covered with rough-cast and its curious features only to be guessed at from a baluster belfry window, and the small rude rag-stone walling of the interior, with the absence of a staircase; but on recently passing through Oxford I was glad to find the rough-cast stripped off from the outside, and its long and short features clearly displayed. It now stands out a decided and good specimen of the long and short work.

15. TRINITY CHURCH, COLCHESTER.

Of this church only a part of the tower, the west door and a small portion about it are of early date, but this small part is curious from its near approximation to Roman work, being plastered over bricks, and also from its having a straight-lined arch. The arch into the church is semicircular and of small ragstones or brick, *i.e.* flat tiles.

16. THE CHURCH OF STOKE D'ABERNON, SURREY.

This church has the chancel arch and east wall of long and short work.

17. THE CHURCH OF NORTH BURCOMBE, WILTS.

This is a small church close by the roadside from Wilton to Hindon; it is only the east end of the chancel which appears

CHURCH OF NORTH BURCOMBE, WILTSHIRE.
East End of the Chancel and Returns.

to be part of the original building, though the rest of the church is principally of Decorated date, and has proper quoins of the usual size and alternate bonding into the wall, and thus this church offers a good specimen of both sorts of masonry which are not commonly found together.

Both the long and short pieces and the quoins are of the oolite common in that part of Wiltshire, and are in very good condition, and the edges sharp, affording another proof of the value of that description of stone. The walls are flint and rag

Quoined work.

Long and short.

and some rubble, but the east end is plastered and rough-cast, as well as part of the sides of the chancel, and therefore I cannot tell whether there is any east window, or ever has been, as the plaster, both inside and out, shows no trace of any that I could discover.

18. BRITFORD CHURCH, NEAR SALISBURY.

In this parish was, I believe, a palace of Edward the Confessor. The church is a cross church, and seems to have been rebuilt and patched at various times, but there still remains a north and a south door, which are evidently Saxon, and there is another aperture rudely stopped, and a window, also stopped, with a buttress of much later date before it. This last-mentioned aperture and window are not clear as to date, but the north and south doors are curious. The former is of stone in small thin pieces, long and short wise, with a plain impost to spring from; the latter is also composed of long and short pieces of stone, with a few of the flat tiles called Roman bricks, and the arch turned with these bricks, and large joints of a mortar evidently composed of lime, flint and pounded bricks. These doors are now both stopped. The south door forms an important link with Brixworth Church by the mixture of brick and stone.

19. THE CHURCH OF WORTH, IN SUSSEX,

appears to have some long and short work, but as I have not been yet able to visit it, or otherwise to ascertain exactly its arrangement and construction, I notice it only as a church deserving of more attention than it has hitherto received.

20. SOMPTING CHURCH, SUSSEX.

This most curious tower I have recently visited, and have found it clearly of long and short character, but presenting some singular differences from others. Here, as in most, the corner-stones are long and short, but the transverse or short pieces are no longer, or rather broader, than the long ones, and they are mostly of a different stone.

Ordinary long and short.

Long and short at Sompting.

This tower is large, and the whole of the north side has been taken down and rebuilt to form a side of a chapel, part of which now remains, but this only applies to about fifteen feet of

the lower part, all above is ancient. There is a window, now stopped, on the west side of this tower which appears to be an original one, and which has the small thin long and short work, like the north door at Britford. The opening into the church from this tower is not in the middle, but on the south part of

the west wall, and has on each side a column and two pilasters; the former with a rude capital not Norman, but having much of a Roman character, and like a Corinthian cap with the volutes and curls of the leaves broken off; the pilasters have a sort of impost with a boldly cut scroll, the relief and character of which are also much more Roman than Norman. This tower has no stairs, and in its upper windows has a plain round centre instead of the baluster, but having a top with a rude sort of volute, and in several parts of these windows I found Roman bricks, or flat tiles, and some of the windows had semicircular heads and some straight-lined heads.

This tower has a middle rib which becomes rounded above the first storey, and is flat below; that first storey has over it an ornamented string with a sort of cutting I have never seen elsewhere, and unlike any Norman ornament.

This string is about 9 inches thick, and is so decayed that I could not satisfactorily ascertain its section, but I believe the above is near what it is.

This tower is lofty, full 100 feet to the point of the slated sort of spire; it has four gables very pointed, and thence arises the spire.

The church is a cross church with no aisles, except an east aisle to the transepts; the north has three round piers and two arches, and the south one arch only; the whole of this is mixed with very late Norman and Early English, and appears all before 1200, except the woodwork of the porch and perhaps its stonework, and some Perpendicular inserted windows. On the whole, this is a very curious church, and deserves to be studied with great attention.

Having now gone through the list of twenty churches which I have described with some minuteness, in order to excite an interest in this valuable study, and also to show their connection (and I have left much undescribed, that they may be visited and studied by others), I proceed to make a few general remarks.

I beg first to say that in this interesting investigation I owe much to the zeal and activity of my friend William Twopeny, Esq., of the Temple. For the knowledge of several of these churches I am indebted to him; he first discovered and

examined the two extremes, Whittingham and North Burcombe, each of which I have since visited, and found peculiarly valuable.

It is curious that of twenty churches the names of seven, or more than one-third, begin with the letter B.

It is also curious that no one of the towers appears to have had a stone stair. Those at Brixworth and Brigstock are evidently additions outside, and at Barnack obviously so inside. They have all ladders, and I find no vestige of any original stone stair; at Whittingham is a sort of vault and rude stair a little way up, but I do not think it original. The very extensive under-building which appears at Earl's Barton to introduce the arch into the nave, and at Sompting to add the decorated side chapel, are very curious, and show great boldness of practice. In the latter, short and thick buttresses have been added to the tower, evidently when this chapel was built; and a west door and window inserted in the lower storey of the tower at the same time.

The term Roman brick will, I hope, be easily understood. Though I by no means wish to assert that all these bricks were Roman, I think it not unlikely that the Saxons retained the art of making them. The brick I mean differs in shape from modern brick, and more resembles our present large paving tile; they are of various dimensions, nearly, but I believe seldom quite, square, between 14 inches and 11 inches on the sides, and rarely much more than 1½ inches thick.

As the terms "rag" and "rubble," though very clear when known, are sometimes confusing to those not acquainted with various masonry, I may say that by rag I mean stuff of many qualities in different counties, but being flat-bedded stuff, breaking up about the thickness of a common brick, sometimes thinner, and generally used in pieces not much larger than a brick, it is found laid in all directions, though generally horizontally. This stone is often very hard, and frequently plastered and rough-cast; but in some counties neatly pointed with large joints and looking very well. Rubble walling is generally of pieces more nearly approaching to a cube, with great irregularity of size and shape, as well as hardness. This also is often plastered, but sometimes well pointed with large joints, and

left outside; it is, however, much more used as backing behind ashlar work, and often of very bad materials. I once took down a fine Norman tower, in parts 7 feet thick, and the wall consisted of two skins about 9 inches thick of sandstone ashlar, and the whole of the interval filled in with mere mud mixed with a little lime. In all these early churches the materials are generally hard and well consolidated.

I fear I have occupied too much of the valuable time of the Society, but I could not well compress what I had to say in less compass, and I was desirous of presenting at once to the view of the members all that I at present know on the subject, that others may be induced to engage in this interesting pursuit, and thereby my list of twenty churches be increased, for there are several others that I hope will, on careful examination, prove to be of this early date. I do not mention them, because I wish not to mislead by noticing what may be curious; but rather, that by closely studying these examples, the student may have his ideas of this style carefully fixed, and then explore for himself in the many parts of England where our churches have not, to any extent, been properly examined.

As I wish not to delay this paper, I have not been able to prepare drawings for so many as I could desire; but this is the less important, as the examples not drawn are mostly engraved in various architectural publications.—I remain, thine truly,

THOMAS RICKMAN.

MITLA'S ONE MYSTERY.*

THE present village of Mitla may be said to occupy the site of the ancient city of Mitla, if there was such a city, which is by no means certain. A little river, which swells inordinately after heavy rain, runs through the centre and divides it into north and south, the ruins being in the former section, partly mingled with the small houses and gardens of the present inhabitants. Their numbers, fortunately, are not great, being a little under 2,500 persons, or otherwise nothing would be left of remains which are in some respects the most interesting in the world, for, frankly, I believe that there is not a house in the place whose walls were not built with stones taken from the palaces of Mitla. I call them so, not that I believe them to have been palaces, but because the name has been given to them, and will probably stick. The Indians call them the forts of Pezelao, and Father Burgoa in a work which he wrote upon the State of Oaxaca, and which was printed in Mexico in 1671, calls them cemeteries, probably from traditions related to him by the Zapotien Indians.

But it is highly probable that the name of palaces was restored by the first Spaniards who came into this region, and who left peculiar traces of the ardent admiration which they felt for these structures. They built a church in the court of one of them and established the residence of the curé or priest in the small halls which connected with the patio, putting on roofs and repairing here and there slight breaches in the walls. They took every stone from a truncated pyramid about 35 feet high and built a small calvario on its platform, turning its patio into a village cemetery. Then with the stones, which were all treads and risers, they endeavoured to build a wall on the same principle of construction as that used by the unknown builders of these palaces. This is, I believe, the only spot where the Spaniards practised that imitation which is the sincerest flattery; but their success was far from gratifying, and the wall which is in the presidio or square of the southern and official section of the village is still extant, a monument indeed of durability, but also a proof that the conquerors did not understand the architecture of these ruins in its most essential details.

There were, when Burgoa wrote, four structures independent of the church and the calvario. Of these two are in fairly good condition, one has been divided up into cabins by the people, and the fourth seems to have disappeared totally. As the differences between those that are extant are very slight, it is probable that archaeology has not sustained an irremediable loss by the disappearance of two of the four. All seem to have courts, the halls being arranged around the western ends and connecting with small interior courts. The two that remain are built upon a platform about 6 feet high and somewhat more than that in width, but in what manner access was gained to the platform must be left to conjecture. In all probability the whole structure was surrounded by flights of steps constructed like the pyramid, which was in fact all stairs, and these of so gentle and gradual a rise that tottering infancy and decrepit age could have mounted with comfort.

The walls of the first palace, or that to the north, consist of a central core 6 feet thick, covered by worked stone slabs of less than as many inches. The core is a kind of artificial plum-pudding stone, made of concrete and stones of all sizes. The concrete was made of lime and clay water, and as the clay was black the conglomerate was black also. I could not see

* A communication from Mexico by Mr. Edward Garczynski, published in the *San Francisco Chronicle*.

any part of the foundation, save of the platform. The outcropping stones in the soil had not been removed, but were worked into a compact mass with other stones in their natural condition by a plentiful use of concrete. All the lower courses of stone above the platform have been removed for building purposes, except those at the corners. The probability is that there was one course that slanted like a drip-course, for traces of this are found in both buildings. These rested upon another course, particularly broad, of which there were several, and the last upon a narrow course which rested upon the concrete of the platform. Every stone upon the exterior of this façade fits to the stones above it and below it and on each side of it so exactly that it is impossible to introduce a hair between the joints. They were so thin, in many instances less than 3 inches, and never more than 6 inches, that to keep them in position could not have been effected by the mere contact with the cement of the core. It was necessary to get some pressure on them, and this was done by giving a slight overhang to the wall, which is not the least out of plumb, but was built that way so as to press the stone against the cement of the core.

The wall is divided into compartments by binding courses of worked sandstone invariably yellow. These come out from the core only a few inches, leaving great spaces of cement-covered wall, and these were filled in by a most singular kind of mosaic work on a system based entirely upon geometric forms. The stones are of the same yellow sandstone as the binding courses, and vary extremely in size, some being not much more than a cubic inch, while others are more than a foot in length. It is as certain as anything that is guessed at can be that these mosaic stones were made by the hundred or the thousand, and workmen put them in place precisely as our brickworkers lay brick. There is no particular finish of workmanship about them as has been reported, many showing great hurry or great carelessness. What is singular is that it would have been impossible for the workmen to put them in place, or to put in place the corner-stone and the binding course, unless they had drawings, and unless there was some system of numbering them. The pattern, so to speak, shifts continually, but there is always the same degree of relief and the same result of chiaroscuro.

In the name of art, who were the men who comprehended architectural chiaroscuro in this pre-eminent degree? Not even in Greek mouldings is there the same extraordinary handling of flat surfaces. There is an exact and most beautiful balance between the masses of worked salient stone and the mosaic panelling, and when the sun falls upon the latter it becomes a golden network. The façade of the first palace faces exactly west, and receives all the glory of the setting sun. In this light the visitor realises what mighty men there were in the olden time. The plane surfaces are all aflame, the relief panels become transformed, the lines wriggle like living things and the shadows are full of suggestions and mystery. Then does he comprehend that the men who planned these buildings belonged to a higher civilisation than ours, and that they made their structures a part of the landscape.

The system of decoration, external and internal, is all geometric. The inner court of this palace affords an excellent example of Mita mosaic relief. Almost all are modifications of the zigzag which used to be called the Grecque, because the idea once prevailed that it was a Greek invention. It is seen on one of the mouldings of the principal pediment of the Parthenon. But it is far more Mexican than Greek, and if it was not indigenous here, which is possible, it certainly was carried from this continent to Europe. The steady tendency of most advanced modern thought is to connect Mexico with the Chinese, Japanese, Hindoos and Persians; but it is immaterial in what way this connection took place, because it is difficult, if not impossible, to reconstruct the continents and oceans as they were before the last cataclysm in the year 1000 B.C.

I regret exceedingly that I was unable to secure a photograph containing the mosaic panelling of the zigzag with a small Maltese cross in the centre, which is to be found in one of the halls. Many readers refuse to believe that the cross continually recurs in Mexican antiquities. The very famous cross of Palenque is so turned and twisted and scrolled and decorated that those who deny it to be a cross and assert it to be a tree are not without some show of reason. But at Mita there is an entire panel of Grecque mosaics, in the centre of which is a plain cross with all the arms of the same length. On the lintels of the entrances the geometric designs are sculptured in low relief upon the stones, which are of enormous size and weight and are supported by large monolithic jambs, but the latter are undecorated. The lintels go very far beyond the jambs, obtruding their ends among the mosaic-work, and the two match so exactly that it is only by following the lintel with the eye that one can tell which is which. In some of the interior walls there is a marked inferiority in the planning, for no care was taken to make the corners come out even, and the workmen seem to have settled the matter by breaking the

mosaic stones to make them fit the space without paying any regard to the look of the work.

I cannot leave this branch of the subject without pointing out that the exclusive use of geometric designs in decoration, outside of Mexican antiquities, has hitherto been found only in Phœnician bronzes in Ireland and Scandinavia, the only two regions in which these bronzes occur numerous. Archæologists have been so accustomed to accept this as axiomatic that the question has been raised whether bronzes with leaf decoration found in those two localities should not be considered as of another origin. No analysis has been made of the bronze to determine the fact, because all Phœnician bronzes vary in the amount of tin, ranging from 10 to 14½ per cent., and the mere appearance of these objects shows clearly that they are an amalgam of copper and tin, and contain neither lead nor zinc, like Etruscan and Greek bronzes. It is not good science to have one general law for European archæology and another for American. If the standard with regard to geometric decoration is worth anything, then these buildings must be Phœnician.

One of the halls of the north palace has a row of columns running from end to end. They measure 11 feet in circumference and are about 17 feet high. These appealed strongly to the imagination of Father Burgoa, who wrote about them as if they were something very wonderful. I cannot admire them, nor can I believe that they were a part of the original structure. They are of a tetzoube or volcanic tufa, much like basaltic rock. They are black cylinders, so to speak, and no more, having neither base nor capital. If, as Burgoa wrote, they supported a roof, then the latter also must have been an addition, taking the place of something that had been destroyed. If we regard these shafts as having been made by cave-dwelling savages, and the Zapotians were nothing more, then we must wonder at the industry with which men with only the appliances of neolithic man worked these monoliths into shape. But they would not have done this without some inspiration, some model, and these columns resemble very exactly the two which were in the great Phœnician temple of Gadir, now Cadiz. In the centre was a rude unworked cylindrical stone, which represented Asto or the Sacred Tree, and on each side were these two columns in bronze without bases or capitals, and they were known as the pillars of the two Hercules, for there were two, one with a goat skin, the other with a lion's skin. Their memory is still preserved in the dollar mark. For some reason the Spaniards removed one of these columns from another part of this palace, for they occur in other places besides this hall, and deposited it in the village presidio. But they broke it in transit.

CADDINGTON.

THE members of the London Geologists' Association and of the Herts Natural History Society, to the number of about fifty, held, the *St. Albans Times* says, an interesting field meeting on Saturday, the 2nd inst. The archæological department was conducted by Mr. Worthington G. Smith, F.L.S., of Dunstable; the geological by Mr. A. C. G. Cameron, H.M. Geological Survey, of Bedford; and the botanical by Mr. James Saunders, of Luton. The company assembled at the Midland Railway Station, Luton, whence they proceeded to the parish church, the inspection of which furnished many points of interest. The construction of the tower, which is of Tottenhoe stone and upper chalk flints in alternate cubes, thus illustrating the use of local materials in its construction, was commented upon. In the interior, the ancient font, its ornate canopy, the Wenlock chapel, the fine oak carvings and the quaint inscriptions on some of the tombs occupied attention during the brief visit. The company then walked through Luton, by Farley Green to Woodside and Slip End. Between these villages are some excavations for brick-making, to which Mr. W. G. Smith conducted the company, and some half-dozen others lying near Caddington, in which that gentleman has discovered an old Palæolithic land surface surmounted by relict Tertiary and contorted red drift. It was the opinion of Mr. W. G. Smith, as the result of long and careful investigation, that an ancient lake existed at this place, and the primitive inhabitants, who lived either in huts by its shores, or possibly constructed on piles above its surface, have left many relics attesting their occupation of the site. These consisted chiefly of flint flakes of all kinds, most of which have edges nearly as keen as knives. Many hundreds of these, as well as numerous well-formed flint tools, have been brought to light, specimens of which are in the collection of Mr. W. G. Smith, at Dunstable. That these flakes were made on the spot is shown by the fragments found which have been struck off, and in many instances the gentlemen referred to have, with great skill and pains, reunited the detached portions and built up the flint with a close resemblance of its original form. In one of the pits near Caddington numerous fragments of Roman pottery have been discovered, and in other places in the neighbourhood cinerary urns, stones used, when heated, for

pot-boilers, and numerous other relics of the ancient and prehistoric inhabitants have been unearthed, and now form part of the extensive collections of antiquities which may be seen at Dunstable. Between Caddington village and Zanches farm a Saxon tumulus formed an interesting object for inspection. Close to Zanches farm is an old pasture believed to have been a place for making bricks or tiles in Mediæval, or perhaps Roman, times. It was pointed out that in the construction of the farmhouse, notably in the chimney, Roman tiles were used, which may have been obtained from excavations on the site, or from an older building which the present edifice has replaced. From this point the company walked to Blows Farm, at which place some hollows in the hillside were pointed out, which were the remains of early British hut foundations. Deep excavations were made by these primitive inhabitants, which were roofed in by skins, &c., these hollows forming more effective shelter than tents erected on the surface. From this point, some 600 feet above the sea-level, is an extensive view to north and west, embracing Dunstable, the Five Knolls (ancient tumuli), Kensworth Hill, 800 feet on the middle chalk, Totternhoe, with its evidences of early British and Roman occupation, the two Roman roadways, namely, Watling Street and Icknieldway, which cross each other at Dunstable, and beyond a gault plain bounded by distant hills of lower greensand. A smart shower now rendered it imperative to seek the shelter of an establishment at Dunstable, where substantial refreshments were provided for the weary excursionists. At the close of the repast, the President of the Geologists' Association made a complimentary speech upon the effective manner in which the arrangements for the day's proceedings had been carried out, and a vote of thanks to Mr. Worthington Smith was carried by acclamation.

ENGLISH ARMOUR.

OF the military equipment of the Saxons and Normans, who in the year 1066 contended on the coast of Sussex for the mastery of England, and of their immediate descendants, a few corroded swords, blades, single spurs and bosses of shields may be said to be the only relics that have been handed down to us. Even the best authenticated of these cannot be precisely dated, and, if they could, would furnish us with but little useful information. It is from the illuminations, rude as they are, in the MSS. of the eleventh century, and that most interesting and fruitful subject of antiquarian controversy, the Bayeux tapestry, that our imperfect knowledge of the armour and weapons of that period must be drawn, confused more than assisted by the vague expressions to be picked here and there out of the prose and poetry of contemporary chronicles and romances. Whether the "Gehringed Byrn" of the Anglo-Saxon was composed of metal amulets forming a garment of themselves, as is darkly hinted by Bishop Aldhelm in his enigma "De Lorica," or stitched flatly on a tunic of quilted linen, cloth, leather or other material, remains still to be proven. An inference favourable to the latter hypothesis has been drawn from the fact that not the smallest fragment of such a garment has yet been discovered, as it is fairly presumed that the linen or leather having decayed, the rings would drop off, be scattered, lost, or used for other purposes. On the other hand, we may actually be in possession of some ringed byrn without knowing it, as it would be impossible to give an exact date to many of the pieces of chain which are occasionally brought to light. The same observations may apply to the early Norman hauberk (halbers), which, judging from the pictorial representations of the period, was composed not only of rings but small plates of various forms, and studs and bosses, which must have required the support of some other and flexible material. With the hauberk of linked chain, which in the course of the following century became the principal defensive body armour of the knight throughout Europe, was worn a large, cumbersome, cylindrical flat-topped helmet (the heaume of the Normans), with a transverse opening for the sight only. The heaume, with a grated vizor opening with a hinge, continued to be used during the reign of Edward I., but towards the close of it the crown of the heaume became convex, and, finally, conical. To the hauberk of chains, chausses (pantaloon) of the same material had been added in the twelfth century, and to both were now superadded protections of plate. Poleyns for the elbows, and genouilliers for the knees, appear during the latter half of the thirteenth century, and greaves or bainbergs for the legs are seen in painting and sculpture, and named in wills of that period. The war helmet of the fourteenth century was worn with or without a vizor, and attached to it was a curtain of chain to protect the neck, called a camail. Over it, the vizor being removed, was worn the ponderous heaume, the crown of which had taken the conical form necessary to fit the bascinet, and was surmounted by the torse or wreath of the wearer's colours and his crest, which is never seen on the bascinet. In the reign of Richard II. a singularly-formed vizor was attached to the bascinet. Varieties of it, some beaked like a

bird, are to be seen in sculpture and painting from that period to the middle of the fifteenth century. The reign of Henry V. is chiefly remarkable as the era of complete plate, which during the fourteenth century had been gradually superseding chain, but we are still without authenticated portions of the body armour of that date. Feathers were also first worn upon the apex of the bascinet about the same period, that head-piece assuming occasionally a more classical form, resembling the ancient Greek helmet. Several examples exist of the armour used in the reign of Henry VI. The back and breast-plates were of an elegant form. The toes of the steel shoes (sollerets) were sharply pointed, a fashion which, towards the middle of the fifteenth century, was carried to the most extravagant length. The successor of the bascinet was called the salade, or sallet, from the Italian "celata," the face being protected by a large chin-piece, called the "house col." The shield had an opening at the side, called the bouche, for the passage of the lance. The shank of the spur at this period was extremely long. During the reign of Edward IV. greater attention appears to have been paid to the defence of the knight in the tournament. Additional pieces were invented to protect nearly every part of the body, and fastened by screws over the ordinary suit. The close helmet, with vizor and bevor, also appear during this reign, and gradually superseded the vizored bascinet and the salade and hause col. The short reign of Richard III. seems to have been only distinguished by the more elaborate ornamentation of armour, particularly of the elbow and knee pieces, which display large fan-like terminations; but it would be difficult to assign positively any piece of armour to the period within the three years of his domination, and the next great change must be attributed to the accession of Henry VII., of whose reign pass-guards at the shoulders, fluted suits with short waists and very globose breast-plates, sometimes also finely engraved, are the principal characteristics. The suits of Henry VIII.'s time are principally remarkable for the form of the breast-plate, which presents a salient angle called the tapul, and of the solleret, which assumed a breadth at the toe as extravagant as was the point in the previous century. In fact, armour appears generally to have followed the fashion of the civil attire, and the square-toed shoes of this reign, the puffed, slashed and ribbed doublets, and the full, fluted skirts or bases of them, are all to be seen imitated in steel. One of the distinguishing features of the sixteenth-century armour is the gradual descent of the angle of the tapul before mentioned, from the centre to the very bottom of the breast-plate, till the point projects in a curved or beak-like form immediately over the waist-belt. In the next century it entirely disappears. Another characteristic is the superb ornamentation which the revival of art on the Continent extended to the craft of the armourer. An open head-piece called a morion was very generally worn during the sixteenth century. These were also elaborately engraved and embossed. The use of armour gradually decreased during the seventeenth century, the improvement in firearms, perhaps, being the principal cause. Armour for the legs and feet was abandoned in the reign of Charles I., and by the time William of Nassau landed at Torbay little remained of the iron panoply of war beyond the breast and back-plate.

ARTS AND CRAFTS IN IRELAND.

THE Council of the Royal Institute of the Architects of Ireland having considered the proposal for an arts and crafts exhibition, in Dublin, have come to the following conclusions on the subject:—

That the Institute of Architects most cordially welcome a well-organised exhibition to stimulate development of arts and crafts in Ireland by Irish hands.

With respect to those arts and crafts subsidiary to or related to architecture and building, this Council is of opinion that it would be a praiseworthy object of such an exhibition to do justice to the high standard of excellence attained in some leading crafts, and to bring into recognition the individual authorship of such craft as is honourable to Ireland, such crafts being more pre-eminently stone and wood sculpture, wrought metalwork, and plaster modelling for reproduction in stucco-work, metal or other materials.

The Council must, however, recognise that by far the most important function of an arts and crafts exhibition in Ireland would be to mark those other arts and crafts which have either disappeared from or have never been introduced to meet modern demand into Ireland. It is to the constant regret of architects that money is diverted under their hands to England, Scotland and the Continent because there is no production of such art and craft in Ireland at the present time to meet demand.

Such arts may be classed as glass-painting, encaustic tiling, paper-hanging, design and printing; lincrusta wall and ceiling, lining papier maché, fibrous plaster and such pressed moulded appliances, mosaic in its several applications to walls,

ceilings, &c.; mural decoration in painting, sgraffito and other media; terra-cotta work, lockmaking and lock and door furniture, and all used and decorative ironmongery belonging to buildings; sanitary appliances and goods of every sort, cast-iron work of every ornamental and ordinary kind commonly incidental to a building, &c.

In the opinion of this Council, who are well informed as to the practical non-existence of such arts and crafts and others in Ireland, an exhibition which would not be educational comparative of Irish work with its rivals, and with a special end to revive lost crafts and introduce new ones into Ireland (among which there are some definitely suited to female employment), would be futile and even mischievous.

Resolved—That while sympathising with the Earl of Mayo's patriotic scheme of an arts and crafts exhibition, the Council of the Institute of Architects shall await the definition of a scheme on comprehensive lines and of practical management, under which mere manufacturing advertisement may be discriminated from genuine art craftsmanship.

When assured of practical advantage to arts and crafts, with architecture and building, the Council would desire their President to represent architects in co-operating in such a movement.

ST. ANDREW'S CHURCH, NEWCASTLE.

At the last monthly meeting of the Newcastle Society of Antiquaries Mr. S. Thorpe said he wished to call attention to the alterations at St. Andrew's Church, Newcastle. It appeared in opening out the Holy Trinity chantry they had come upon the tomb of Sir Aymer de Athol. He had heard that it was proposed to lower the floor of the chantry to the level of the floor of the church. Now the church floor was already about a foot higher than it was originally, and if they were now to lower the floor he thought it would spoil the effect altogether, and besides, it would disturb the tombstones that were now laid. It would be a pity to do so. It was also suggested that a layer of concrete should be laid over the whole.

The Secretary thought some of the gravestones found were most interesting.

The Chairman asked if Mr. Thorpe had any authority for the statement he had made.

Mr. Thorpe said they were carrying away earth from the place now. Perhaps the Chairman could give them some information.

The Chairman said he knew nothing about the affair—nothing more than he had seen in the newspapers.

Mr. Knowles said the excavations revealed several tombstones, including that of Sir Aymer de Athol. If no other member of the Society was interested in the matter, he would be very glad to measure and indicate the position of the stones and to record the inscriptions. He had simply glanced at the articles in the *Newcastle Chronicle* that morning, and he gathered that they had fallen into the usual mistake that St. Andrew's was the oldest church in Newcastle. This was not correct, for at St. Nicholas's and St. John's they found the oldest foundations. The only portion of the brass taken from the tomb of Sir Aymer de Athol was now in the Black Gate. It would, perhaps, be well to record all that was to be seen in the chantry of St. Andrew's, and, if no other member was concerned in the matter, he would be glad to do what he could. He would see the architect of the alterations, and if he was not going to make the record, he (Mr. Knowles) would be glad to do so. The tomb found there was, no doubt, contemporary with the work of the fourteenth century.

The Chairman thought the offer of Mr. Knowles was a valuable one, and one which they should accept. In regard to what Mr. Thorpe had said about moving the stones or covering some of them up again, he thought they should really gather some information with reference to that.

Mr. Knowles thought that was a mistake on the part of Mr. Thorpe. There was no vandalism, he imagined, contemplated.

Mr. Thorpe said he had heard it was suggested to cover them with cement.

Mr. Wm. Vincent, one of the churchwardens of St. Andrew's, said that Mr. Thorpe had been misinformed. He might say for himself, for the vicar and his fellow-churchwardens, that their wish was to have everything of antiquarian interest most carefully protected, and in any way they could they would take the greatest possible care that no injury was done to anything that was found. They had made special arrangements with Mr. Hicks, architect, to the effect that everything of antiquarian interest should be taken the greatest care of. So far as the contract was concerned, if they happened to come across anything that would indicate any of the old building, and possibly the lost chantry, which they thought might stand upon the present vestry, it was decided that the contract might be altered so that they might pay for any differences in work. So far as the De Athol tombstone was concerned, he might say it had been suggested by one of the churchwardens, Dr. Arnison, that a cast should be taken, which the churchwardens

might either take care of themselves or give to the Society of Antiquaries, though he did not promise the latter. They wished to have the tombstone so protected that they might know where it was. They might depend that every care would be taken in the work. Mr. Thorpe had made some reference to lowering the floor. They did not expect, in lowering the floor of the chantry to the level of the floor of the chancel, that they would do any injury to anything. Indeed, they had such an able architect to direct their operations that they might be sure nothing would be done to do any harm. Speaking for himself, he had a great deal to do with what was going on, and if Mr. Knowles cared to co-operate with him he would be glad to assist him as far as possible.

GENERAL.

Messrs. Woodhouse & Willoughby have been successful in the competition for the Castlemere School for the Rochdale School Board, which will cost 5,000*l*.

A Church of the fifth or sixth century, 120 feet in length, has been discovered in the course of excavations at Tigzait, near Dellys, Algeria. There are numerous carvings on the walls, and in the apse are many Pagan stelæ, apparently showing that a temple originally stood on the site. The monogram of Christ is profusely employed on the carved pillars.

An Inquest has been held at Kensington upon the remains of Mr. W. Conradi, an architect, aged sixty-four. It appeared that he was engaged measuring the interior of Watford Church, and, slipping from a pew, fell to the ground. Mr. Conradi succumbed to shock from internal hæmorrhage from injuries sustained through the fall. A verdict of "Accidental death" was returned.

The Dean and Chapter of Peterborough Cathedral have given instructions to Mr. Pearson, R.A., to proceed with designs for a memorial to Queen Catharine of Aragon, to be placed in the cathedral. The Dean and Chapter have also decided to erect there a memorial to Mary, Queen of Scots, her body having for a short time lain in the cathedral.

An Ogham Stone, inscribed with novel characters, has been found in Deracrin, co. Louth. Hitherto memorials of that class were only found in the southern districts of Ireland.

The City Commission of Sewers decided on Tuesday that Mr. D. J. Ross, who since 1882 had been chief assistant to the late engineer (Colonel Haywood) and twenty-two years in the department, should be appointed chief of the engineer's office, with power to call in consulting advice under the authority of the court when deemed expedient, and that his salary, now 650*l*., be increased to 900*l*.

Alderman Gibson, Newcastle, has given 3,000*l*. towards the erection of a building at Gosforth, to accommodate the beneficiaries of the Diocesan Home of Mercy. The building and site will cost over 8,000*l*.

Turner's "Ancient Italy" has been purchased by some French amateurs and presented to the Louvre. It is an important addition to the few works which represent English art in the galleries.

The Merchant Taylors' Company have let on a building lease, for the purpose of being pulled down, the exquisite vaulted early fourteenth-century undercroft at No. 3 Laurence Pountney Hill, the only known specimen of that kind of domestic architecture now remaining in London.

A Statue of the late Cardinal Lavigerie is to be placed in the public place of Bayonne, his native city. The initiative of the project is to be credited to M. Bonnat, the portrait-painter.

The Honorary Degree of D.C.L. is to be conferred by the University of Oxford on Mr. John Henry Middleton, M.A., Exeter College, Fellow of King's College, Cambridge, director of the South Kensington Museum, Slade Professor of Fine Art in the University of Cambridge; and Signor Rodolfo Lanciani, professor of Roman Topography in the University of Rome.

An Exhibition of ancient and modern industrial art will be held in Copenhagen from July 15 to September 30.

Mr. T. de Courcy Meade was on Wednesday elected city surveyor of Manchester.

Messrs. Paley, Austin & Paley have prepared plans for the restoration of Farnworth Church, and a faculty has been granted for carrying out the work, which it is estimated will cost between 3,000*l*. and 4,000*l*.

A School of Art and free library is proposed to be built at Brierley Hill, and a committee has been appointed to consider the subject.

The Annual Excursion of the Lincolnshire and Nottinghamshire Architectural Society took place on Wednesday, when the churches of Ashby Puerorum, Somersby, Salmonby, Tetford, Ormsby, Harrington, Bag Enderby, Hagworthingham, Lusby, Bolingbroke, Mareham-on-the-Hill and Scrivelsby were visited.

The Architect.

THE WEEK.

By the accidental death of Mr. ARTHUR CAWSTON, in his thirty-seventh year, on Friday last, an architect who appeared to have a most prosperous career before him has been lost to the profession. He was a man who was endowed with peculiar energy, and having moreover the advantage of influential friends, his success might be considered as assured. His project to improve London by the formation of boulevards and other costly works was characteristic of his ambitious temperament. Mr. CAWSTON's own works did not err by extravagance, for they were all kept within due bounds. The new Home for Incurables on Streatham Common, which is ready for opening, was an example of his competence to erect large buildings. Another important work is the market at Carlisle, which he carried out in connection with Mr. GRAHAM of that city. Mr. CAWSTON was architect of the Church of the Ascension, Balham, with the vicarage; the church of St. Luke, Bromley Common, and St. Philip's Church, Stepney. He also designed houses at Bromley, a mansion at Marden Park, and a mansion and farm buildings at Paddockhurst, Sussex.

In the course of the Rede Lecture, delivered in Cambridge on Wednesday, Mr. J. W. CLARK, M.A., described the arrangements of Mediæval libraries. The books were generally kept in the cloisters and were shut up in presses. The Durham Rites spoke only of book-presses standing in the cloisters against the walls; but it was not unusual to have recesses in the wall itself, fitted with shelves, and probably closed by a door. Afterwards a definite room was constructed for books, in addition to the presses in the cloister, which were still retained for the books in daily use. This library was not unfrequently thrown open to scholars in general, who were allowed to borrow books from it, on execution of an indenture or deposit of a sufficient pledge. When books were first placed in a separate room, fastened with iron chains, for the use of the fellows of a college or the monks of a convent, the piece of furniture used was probably an elongated lectern or desk of a convenient height for a seated reader to use. The books lay on their sides on the desk, and were attached by chains to a horizontal bar above it. There were at least two libraries in Cambridge University fitted with such desks—at the colleges of Pembroke and Queen's, and that it was a common form abroad was proved by its appearance towards the end of the fifteenth century in a French translation of the first book of the "Consolations of Philosophy" of BOETHIUS. The desk could not be dispensed with so long as books were chained, but one or more shelves were added to it. The system of chaining, as adopted in this country, would allow of the books being readily taken down from the shelves and laid on the desk for reading. One end of the chain was attached to the middle of the upper edge of the right-hand board; the other to a ring which played on a bar set in front of the shelf on which the book stood. The fore-edge of the books, not the back, was turned forwards. A swivel, usually in the middle of the chain, prevented tangling. The chains varied in length according to the distance of the shelf from the desk. The bar was kept in place by a rather elaborate system of ironwork attached to the end of the book-case. In English libraries at least bookcases arranged on what he might term the Oxford type were in general use throughout the sixteenth and seventeenth centuries. The invention of printing had largely increased the number of volumes, and at the same time diminished their value, so that chaining was no longer necessary. When it had been abandoned neither a desk nor a seat in close proximity to the books was required. In consequence, though libraries continued to be built on the ancient type with numerous windows close to the floor, it was possible to alter the old cases or to make new ones with a far larger number of shelves than heretofore, and when further space for books was needed low cases were interposed between each pair of tall ones. So far as Mr. CLARK

had been able to discover, the first library arranged in the way with which we were familiar—namely, with the bookcases set against the walls instead of at right angles to them—was that of the Escorial. Among the imitators of this, he felt sure, was Cardinal MAZARIN, whose library was fitted up in Paris shortly after 1643 in order to be used daily by the public.

An important improvement will shortly be undertaken in Sheffield. The High Street is to be widened at a cost of 260,000*l.*, and the money could not be more wisely expended, for as a thoroughfare it is not worthy of the new city. There are eighteen owners of property, and already the City Council have been able to arrange with sixteen of them. That means securing 2,556 square yards. Possession of five of the properties can be obtained at once. The leases of the remainder will expire between the present time and 1897. The Corporation are prepared to consider offers to surrender at an earlier date. The properties have been acquired for sums which are below the valuer's estimates.

THE people in the North have a certainty that they will not be overcharged when the "measuring up" is conducted by one of the regular measurers. It was therefore a waste of money when a plumber's bill for 79*l.* was disputed in the Glasgow Sheriff's Court on account of inaccuracy. The work was done in connection with alterations of property at Dowanhill; it was measured by Mr. WILKIE, who had prepared the schedules of quantities, and certified by Mr. TENNANT, the owner's architect. But the owner declared that the measurement was essentially erroneous and misleading; that the quantities were taken from the statements of the plumber, and were not verified; that in many instances they were in excess of the work actually done and of the material supplied; that the prices allowed were excessive, and that in almost every item, which was not expressly provided for in the estimate schedule, the prices were very much overcharged, and not in conformity with the condition of the schedule, wherein it was stipulated that the work should be "charged at the estimate rates or others corresponding thereto;" and further, that in some instances the materials supplied were not correctly described in the measurement, and charges were made which were excessive and inapplicable to the materials actually supplied. After an investigation the defence was set aside, and a decree has been given for the amount sought. That is satisfactory for the plumber. But is there to be no compensation for Mr. WILKIE, against whose professional character so many unwarranted allegations have been made in a public court?

THE committee of judges appointed for that purpose have on various occasions thoroughly considered the drawings submitted by the architects who were requested to send in competitive designs for Christ's Hospital new boarding schools, and they have now reported to the Council of Almoners that in their opinion each of the designs is of exceptional merit and power. They are unanimously of opinion that the design submitted by Messrs. ASTON WEBB & E. INGRESS BELL most closely fulfils the instructions; that it is the best in point of arrangement, the cheapest to carry out, and is on the whole the most suited for the Hospital's purpose. They have accordingly made their award in favour of Messrs. ASTON WEBB & E. INGRESS BELL.

THE opening address of the meeting of the British Association at Oxford will be delivered by the Marquis of SALISBURY on August 8, in the Sheldonian Theatre, which will be specially lighted by electricity. There will be excursions to Windsor Castle, Dropmore, Taplow Court, Silchester, Reading, Blenheim, Swindon Railway Works, Faringdon, Abingdon, Dorchester, Wallingford, Warwick Castle, Stratford-on-Avon, Wroxton Abbey, Broughton Castle, Edgehill, Compton Wydmattes, Tanford, and probably to other places in addition. Lord WANTAGE, Sir WILLIAM ANSON and other gentlemen will give garden-parties during the meeting.

THE STAIRCASE.

THE ancient tradition about JACOB'S Ladder suggests the simplicity of the primitive means of ascent and descent in buildings. We may assume that one of the difficulties which checked the desire to erect lofty buildings arose from the inability to reach the upper parts. LONGFELLOW, in one of his poems, endeavours to inspire courage in the faint-hearted by pointing out that the giant pyramids of stone, when better known, are found to be only flights of stairs. Although the description is true enough, yet it must be acknowledged that the risers and treads are excessively inconvenient. We might suppose that pyramids were originally suggested by a ladder placed against a house, but of the two means of access the majority of climbers would prefer ladders. Apparently the most approved system of approach for lofty structures in the East was to surround them by an incline. When the decorative value of a great number of steps to form a base for a building was perceived, the inconvenience arising from each being formed of deep stones obtained little attention. The Greeks were not more considerate than other people in the arrangement of steps for the temples.

As even in Babylon the houses consisted of several storeys, there must have been some means of approach from one to the other, but about the character of the stairways we know nothing. They were likely to be very simple. From the absence of information on the subject in the ten books of VITRUVIUS, it might be assumed that fixed staircases did not exist, and that the wise arrangement of ROBINSON CRUSOE of employing a ladder which could be drawn up out of reach was anticipated by the occupants of Greek and Roman houses. VITRUVIUS was, however, somewhat supercilious, and as he appeared to despise a great many things in buildings which could only claim to be useful, probably the staircase was among them. In the Pompeian buildings the important rooms were on the ground floor and visitors never reached a higher level. There were rooms in Pompeian villas which were more uncomfortable than the attics in modern seaside lodgings, and it was of little consequence how they were reached. There is a close connection between architecture and display, and as long as receptions were confined to rooms which could be directly approached from the streets or roads, the staircase was likely to be severely simple in character.

In the early Mediæval period it was necessary to give more thought to security than to architectural appearance. Hence it was that so many staircases were arranged around newels. Their construction is evidence of remarkable skill in the builders which could be easily turned to account in a more imposing way, but the corkscrew stairs compelled an enemy to approach in almost single file, while defence was facilitated. It was probably a desire for security that originated external staircases, which, as the German term *Treppenhaus* still suggests, were considered as independent buildings, although it may now be applied to the interior cage containing stairs.

The Renaissance introduced a more festive character in ordinary life, and in no part of a building was the change more evident than in the arrangement of the staircase. But that change could not be accomplished if war had not also submitted to modifications which diminished the chances of attacks on unfortified buildings. If the Scala dei Giganti in Venice was not the first example of a grandiose treatment, it is likely to have been the earliest which suggested what was attainable to people in other parts of Europe. Venice was the centre of trade where men from distant countries congregated. A modern merchant would concentrate his thoughts on business, but in an earlier time he was expected to do more. NICHOLAS BRETON tells us that the worthy merchant of the Elizabethan period "out of his travels he makes his discoveries, and from his eye-observations brings the models of architectures." The great change which took place in the planning of English staircases will be found to correspond with the extension of English trade by the Merchant Venturers of that period. There was an abundance of timber available, and skilful carpenters to make use of it. Accordingly we find not only construction that has resisted time, but carving that is often carried to excess. The staircase became fascinating

for craftsmen, and on it they exercised such imagination as they possessed. The old hall had been superseded, but the staircase took its place to some extent, for the walls could be lined with ancestral armour and arms; there were also opportunities given for the introduction of heraldic figures and other devices. The staircase also united the galleries, which were an extension of it, and further compensated for the loss of the hall.

Great staircases could not have gained favour in England unless they were adapted to the requirements of life. Like wide entrance-doors, they were suggestive of hospitality. Nothing can seem more out of place in the house of a miserly or a lonely man than wide stairs, for imagination at once pictures them as crowded with a joyous company, and the contrast of their deserted state becomes painful. For a similar reason it is absurd to construct a magnificent staircase to lead to rooms that are insignificant.

As we said before, the staircase is adapted for display, which means of course that arrangements should be made for seeing the people who pass along it. In provision of that kind there is no modern example which is better planned than M. GARNIER'S in the Paris Opera House. The *cage* seems almost like a second theatre, of which the stage or ring is the staircase. Galleries rise above galleries, as if every spectator was entitled to enjoy a second spectacle, which for many becomes the more attractive. The ample space, the graceful curves, the capacious landings seem prepared for a dignified procession of men and women who are expected to allow themselves to be seen. A ticket-holder who is late and hurries along that staircase always appears to be out of place. It is not often that a modern architect can expect to have the construction of so costly a work, and some of the evils of Imperialism should be condoned on account of the liberality which allowed its creation.

It is evident that M. GARNIER avoided straight lines unless where they were indispensable or were useful for contrast. In other staircases in Paris the same love for curves is manifest. The French architects, from their acquaintance with geometry, find pleasure in devising problems which would be puzzling to many "staircase hands" in this country whose winders are rather limited. The esteem for curved lines is not, however, modern, for the remarkable horseshoe steps in the Cour du Cheval-Blanc at Fontainebleau date from 1634.

In England we have grown accustomed to timber staircases, and the raking lines of strings and bearers do not appear incongruous even when they are introduced with masonry. Iron or steel girders, accordingly, are considered to be allowable if they are concealed. But, as everybody knows, there is a limit to the employment of stone in lintels; a similar limit should be observed when the lines are not horizontal. Arches or semi-arches, therefore, are the most appropriate supports for flights of stairs which are constructed of stone. They also suggest how the weight of a staircase is carried, which is not always evident.

ANTONIO CANOVA.

THE influence of fashion in sculpture as in the other arts is remarkably exemplified in the uncertainty which appears to inspire criticisms on CANOVA. He was supposed to have given the death-stroke with his chisel to the extravagance of the school of BERNINI. For that he was considered to deserve the gratitude of all lovers of art. Many of his works have so much grace they might pass for antiques, and if they were put forward as examples of Greek art of a late period they would receive unbounded admiration. But there are connoisseurs who consider CANOVA to have been a man of limited powers, who had the good fortune to appear at a time when his unaffected simple style was a novelty and who gained more success than was his due. His figures are also believed to be more dangerous than those of the BERNINI school, since it is not so difficult to imitate them. In consequence they are supposed to have been the cause of that deluge of characterless things in marble which has overspread Europe, and made "modern Italian" serve as a byword for frivolities that are better adapted to be formed of sugar than of stone.

Criticism of the latter kind is exaggerated. CANOVA is not to be blamed for the errors of hosts of imitators, or of those men who turned his simplicity into silliness. Then again, an artist should be judged by the canons which apply to his special class of work. CANOVA never aimed at exciting terror or any of the painful emotions. There was in him as little of a MICHEL ANGELO as a BERNINI. A kindly man, he was glad to be enabled to please the world, and as he knew that few people were able to appreciate the sublime while everyone could enjoy the sight of graceful forms, he kept to the latter. He produced Hebes, Terpsichores, Graces and Heroes that are more mortal than divine.

If compared with ancient figures bearing similar titles, CANOVA's will be considered as less expressive. He was no deep student of mythology, and it may have been an error to have applied names to his figures that would recall Olympus. We must remember, however, that in Italy a long series of traditions and legends had imparted a sort of familiarity to those beings, and it was the notion of an Italian peasant which CANOVA expressed when he modelled a goddess, rather than those of a modern scholar who believes there are profundities in all things mythological. CANOVA's countrymen could have no difficulty in interpreting the character of his *Venus* who appears surprised when bathing, or his *Venus* who is a suppliant to Adonis. They were as significant as the Pauline Bonaparte type, which was known to be a portrait although called a *Venus Victrix*. When against his will CANOVA's *Perseus* was set up on the pedestal in the Vatican where the *Apollo Belvedere* used to stand, the Italians were delighted. The modern figure seemed to be more of "a swell," and the languor corresponded with that of the fine gentlemen in uniform who were visible on grand occasions in the palace. There is little use in judging CANOVA's figures by antique standards; they will not sustain that test: but if we accept them as Italians of the close of the eighteenth century, in scanty drapery, they become characteristic of time and place. A sculptor has to think more of his patrons than of posterity, and when we know how the old King FERDINAND of Naples insisted on CANOVA's representing him as MINERVA, we are able to realise how lax were the notions of fitness at that time.

The sculptor was not only an Italian by birth, disposition and genius, but he was an example that the old methods of acquiring artistic power in his country were as effective in the eighteenth century as in the fifteenth. He was born at Possagno, in the province of Trevisa. The village is surrounded by marble quarries, and his family, like most of the inhabitants, were quarrymen or masons. It is still a primitive place where old customs prevail. The church, which CANOVA erected, on every festival exemplifies one of them, for the women alone are allowed to enter through the principal door. ANTONIO, in common with the rest of the boys, used chips of marble as playthings, and as soon as his hand had the strength to use a tool he was apprenticed to one of the stoneworkers, TORRETTO, who could build a wall, carve a panel or a statue without any thought of the difference between trade and art. In the church of S. Liberale at Castelfranco there is an *Assumption* by him, and according to tradition the little tower which is his mason's mark was the work of his apprentice. He was a severe master, who insisted on CANOVA's industry, especially when it was found the apprentice was possessed of ability. TORRETTO's rigour is seen in one incident. ANTONIO fell in love with a girl, BETTA BIASI, whose beauty captivated him. A marriage was agreed upon. At that time TORRETTO fancied he would be more successful if he emigrated to Venice, and his apprentices were obliged to accompany him. CANOVA awakened from his first dream of love, and he was no less unfortunate on another occasion.

When his apprenticeship was over there was nothing to call him back to Possagno. His father was dead, his mother had taken another husband, and CANOVA, from her example, may have thought that all women were fickle, and that BETTA was not worth seeking. He remained in Venice and devoted all his thoughts to his art. His patron was the senator FALIERO, who ordered a carving of two baskets of fruit and flowers which were to ornament a staircase. The commission was not important, except as a trial piece. The baskets were successful and, as in an

earlier time, it was assumed that whoever could carve fruit and flowers was competent to produce full-size Classic figures, and a commission was given by FALIERO for an *Orpheus* and an *Eurydice*. They were followed by a group of *Dædalus* and *Icarus*.

It is well to remember that CANOVA had received a training which would not now be considered as more than sufficient to qualify him to be a carver of ornament or a monumental mason. Although he was in Venice he might be considered as being without opportunity to look upon examples of the antique. Fortunately for him, at that time the Venetians had decided to send a new ambassador to Rome. ZULIANO, who was selected, was a friend of FALIERO. The senator, being anxious to cultivate the taste of his protégé, sent CANOVA to Rome with recommendations to the ambassador, and a cast of the *Dædalus* and *Icarus* was also despatched. It is related that the sculptor, a few hours after his arrival, went to the French Academy to draw from the living model. Soon afterwards the cast was exhibited by ZULIANO to a group of artists and amateurs. The treatment was so different from what was common, the group was not admired. GAVIN HAMILTON, the English painter, was however present, and he became its expositor. The originality and simplicity were then admitted, and CANOVA's position was secured. As long as he lived he continued to express his gratitude for the protection which HAMILTON gave at the most critical point in his life. We must not forget that at the time CANOVA was only twenty-two, and might be considered as a rustic who was out of place in a fashionable assembly. He returned to Venice with more confidence than he had when leaving. He was able to have an allowance of 300 ducats, and with that aid he returned to Rome, resolved to educate himself by means of the examples of Greek art.

The ambassador had presented him with a block of marble, and he decided to employ it for a group, *Theseus, the Conqueror of the Minotaur*. It is said that for this work he drew inspiration from the antique monochrome in the Naples Museum, and CANOVA was never ashamed to acknowledge indebtedness of that sort. When the group was finished it was purchased for a public place in Milan; afterwards it became one of the spoils of war, and was carried to Vienna. QUATREMÈRE DE QUINCY was in Rome, and he expressed surprise that such a work could have come from a young unknown artist, for the execution seemed that of a practised hand. Still more remarkable, he considered, was the antique spirit which seemed to impart life to the figure. The admiration may now seem unwarranted, but the critic had been surrounded by so many commonplace or exaggerated attempts, he could not contain his satisfaction on seeing a marble group in which nature was not outraged. CANOVA's *Theseus* might not be godlike, for the figure suggests a combatant who is not far from being exhausted by the brutal strength of the son of PASIPHÆ; but to express an effect of that kind was a great effort for the time. Out of gratitude the sculptor offered the group to ZULIANO, but it would not be accepted. Afterwards he executed a companion work, showing the hero seated on the monster, which corresponds with the subject of an ancient cameo.

The success of CANOVA was assured, for his figures were considered by the connoisseurs to rival those of the Greeks. It was also accepted as inevitable that he must be equally competent to produce all classes of work. His *Hebe*, which is universally known by the casts from it, is not separated by any great distance of time from GANGANELLI's monument in the Church of the Apostles or from the kneeling figure of the aged CLEMENT XIII. (REZZONICO of Venice) in St. Peter's. Busts and colossal groups, Christian and mythological subjects, equestrian figures, and monuments for churches were produced by CANOVA with equal ease. It was only when he occasionally attempted to treat a subject like the *Hercules and Lycas* (which was compared to a quilted mattress), that his contemporaries perceived there was a limit to versatility. Apologists could be found when weakness was exhibited in some other works. Thus, the figures forming part of the monument of the STUARTS in St. Peter's, which are weak enough, are supposed to be more fitting symbols of the enervation of the later representatives of the race than any which a second MICHEL ANGELO could have produced. CANOVA would have been more than

human if so large a quantity of works as he produced were faultless. He could claim credit for fifty-three statues, twelve groups, fourteen cenotaphs, eight monuments on a large scale, seven colossal figures, two colossal groups, fifty-four busts and twenty-six bas-reliefs. A Greek or a Renaissance sculptor would declare that a pair of hands could not operate on so much marble, but, of course, CANOVA could utilise mechanical aids which were unknown at an earlier period.

CANOVA does not appear to have considered the quantity or the quality of his work as remarkable. Throughout his life he seemed to remain the peasant of Possagno whose business in life was to work in stone. He felt no more jealousy towards successful contemporaries nor superiority over inferior men than would exist between ordinary masons in his native district. The world he thought was wide enough and marble sufficiently abundant to afford employment for more sculptors than existed. There never was an artist who was more disposed to praise the works of other men. On one occasion he said, "If the works of ALVAREZ had been in my studio they would not have remained unsold," thus placing a rival on the same level as himself. He set up a tablet in the Church of the Apostles in Rome to record his obligations to the Venetian senator FALIERO, as if without that benefactor's aid he must have remained in lifelong obscurity. He declined a commission for a statue of the Emperor ALEXANDER, in order that he might devote his time to the cenotaph which was to be a memorial of his admiration for VOLPATO, the engraver. The busts of the Italian artists of the sixteenth century forming part of the Protomoteca in the Palace of the Conservators were either executed gratuitously by him or obtained at his cost. When he was granted the Marquisate of ISCHIA, with an income of over 600*l.* a year attached to it, he divided the whole of the money between three of the academies; he founded also studentships in architecture, sculpture and painting, and pensions for needy artists in Rome. Remembering that his first commissions were FALIERO'S for an *Orpheus* and an *Eurydice*, he devised a crest to record that fact, for it was made up of a lyre and a serpent combined. But he never signed his name as a noble; he remained to the end plain "ANTONIO CANOVA."

It was natural that artists should have held him in reverence, and that when he started a church in Possagno, the inhabitants, including women and children, endeavoured to co-operate with him in the works. Nor was the affection for him confined to Italy. One-fourth of the 4,000*l.* required to pay for CANOVA'S monument in Venice was contributed from England, and a similar amount was given by Frenchmen and Germans, who forgot their country on that occasion. The inscription, "ex consolatione Europæ universe," is insufficient, for some subscriptions arrived from South America, thus proving that the sculptor's merits were not unknown in that region.

A still more striking proof of the fascination which CANOVA'S work exercised on all is seen in his relations with the French ruler. BONAPARTE, although he avoided Italy, had dreams about improving the condition of the country to which his family belonged. But he could not, he said, discover capable men. CANOVA could not say he was neglected, because he was neither politician nor soldier. BONAPARTE, when consul, invited the sculptor to Paris and offered him 120,000 francs for a portrait statue. CANOVA accepted the commission, and in due time produced the large nude figure which is now in Apsley House. It shocked BONAPARTE, especially as he imagined that CANOVA was as unable to understand facts as the rest of the Italians, and must have supposed that the victories which amazed Europe corresponded with those of the English prize ring; or, as BONAPARTE expressed it, "CANOVA croit donc que je me bats à coups du poing." But more acquaintance with the sculptor's style would have diminished the surprise. CANOVA from the first had been making antique heroes of his countrymen; for one who had become so remarkable he could not think of a more suitable representation. His figure of BONAPARTE'S sister is a *Venus Victrix*, his portrait of "Madame Mère," the mother of the conqueror, is an imitation of the *Elder Agrippina*, he represented MARIA LOUISA as *Concord* holding a sacrificial cup. CANOVA would not flatter, and when he said that BONAPARTE'S head was of such a character that it

could easily be taken for an antique if represented on a gem, we may be sure that was his conviction. He imagined he was only properly eulogising the warrior when he presented his figure undraped, just as a scholar might consider that Latin or Greek would alone be eligible for the record of his deeds. Although he was disappointed, NAPOLEON when Emperor wished to retain CANOVA in Paris, but the artist was too much of an Italian to care for a strange land. He believed the world contained no cities that were comparable with Rome and Venice. It was to the Academy of Venice he bequeathed his hand and chisel, and to the Church dei Frari his heart.

The relations of CANOVA with the French Emperor brought about one of the most disagreeable incidents of the sculptor's life, but one in which we can trace his desire to judge affairs in a generous way. On the downfall of the Empire he was selected to become a sort of temporary ambassador in order to recover the works of art which were taken from the Roman States. He declined the mission, but as the Pope insisted, he was forced to yield. He endeavoured to carry out his duties without offering much offence to the French, but he was not successful. His concessions to France were likewise unsatisfactory to the Romans, and between all the parties he was made to suffer. It was a relief to him to accept the invitation of the Prince Regent and visit England. He saw much which surprised him, and especially the Elgin Marbles. They were a revelation to him, for he said that no casts, drawings or engravings which he had seen could suggest the beauty of the originals and the absence of hardness, affectations and convention exhibited in them. His admiration produced much effect in England, and was not without its weight in the transactions for the purchase of the sculpture.

THE AMERICAN ARCHITECT OF FASHION.

IN an article on "The Architect of Fashion," published in the *Architectural Record*, Mr. Leopold Eidlitz has the following remarks on one of the latest developments of the profession in the States:—

The architect of fashion is he who aspires to be the fashionable architect. Like the modern politician, the architect of fashion has no convictions, but follows adroitly in the wake of public opinion. His aim is not to be a great architect, but to do a big architectural business, and in this he very often succeeds. Practice with him has in time developed even a positive dislike for architecture in the abstract, for whenever he has attempted it in any degree the result was disastrous from a business point of view.

To do justice to the architect of fashion, let us say here that he was not born so, nor is he conscientiously malicious or even cynical. He is shrewd enough to look after his material interests, and when he finds these inconsistent with the interests of architecture he drops architecture, rather than let architecture drop him. Of course he has abandoned all claim to immortality, to a statue in the Walhalla or a niche in Westminster Abbey, but he enjoys life while it lasts as a highly respectable member of society belonging to the most fashionable clubs, and although at times he gets very tired of it all, because of the humiliation of constant drumming and the silent gnawing of his professional conscience, he has the consolation of success and feels sure of pre-eminence until supplanted by an architect even more eminently fashionable.

To understand him thoroughly, we must permit him to speak for himself:—

"Your talk of architecture as a living art is most delightful, and reminds me of Kugler, Lubke and Viollet-le-Duc and old Ungewitter; but it is not practical. Everybody admires it, but nobody wants it. My interpretation of architecture as a living art is an art by which an architect can live. When I was young and enthusiastic and all that sort of thing, I procured with much labour an introduction to A. X., the great life-insurance president, a dignified old gentleman, who received me in his office after waiting an hour and a half in an outer room. He listened to me over his shoulder while I stood behind his big arm-chair, as he had not offered me a seat, and I repeated with much trepidation a well-considered brief lecture on architecture.

"When I had finished there was a pause of a minute or two, during which he read over twice an open letter he held in his hand; then he turned, with an evident effort to be amiable as far as his rooted dignity would permit, and said:—'Young man, my friend in this letter speaks of you in very high terms as a promising young architect. I dare say you talked art to him as you did just now to me. It sounds well, and is apt to

impose on persons less familiar with the subject than I am. Architecture, my dear fellow, is not a living art. Greek architecture died before Christ, and Gothic architecture before the Reformation, and that is the reason why we need architects well versed in art history to design our buildings. If, as you say, it were a living art, then anyone could do it. Good-morning, sir."

"Now that I am older I know better. I never talk architecture to my clients. When a man is engaged in building a house or a store or a bank, his mind is naturally preoccupied. He doesn't want to be bored with architecture. Besides, between you and me, of what earthly use is architecture to an architect? Let me tell you it is a hindrance to success. What a man of business wants to know is that you can do the thing you undertake to do well and promptly, and the only way to convince him of that is to tell him so. For instance. After listening attentively to the wants of my client I say modestly, 'I believe, sir, that I now have your views regarding the building, yet I cannot be quite sure of that. You have matured the matter in your own mind. To me many of the features are quite new though intensely interesting. I must ask you to grant me another interview, perhaps two or three after I have commenced plotting it out on paper. When I have fully mastered the subject as you have, then the work will go on rapidly. I do not expect to succeed with a first sketch nor a second nor a third or perhaps a tenth. I throw them off at the rate of two or three in a day, and reject all until I am satisfied. When once satisfied, however, I am sure you will have a design as near perfect as the human mind can produce. I then put from ten to twenty draughtsmen and two or three clerks upon it at once, and in two weeks from now we can proceed with the building. I need only six months to build it in. I can do it in five if need be. A client of mine said to a mutual friend of ours, 'What I like in him is his promptness. He knows what he is about, and he tells you at once what he can do and what he can't do.'"

As to style, the architect of fashion continues:—"It is wisdom to confine yourself to the vernacular. It is the only idiom which is popularly understood; not exactly understood, but, I should say, tolerated by public opinion. Ever since the beginning of the sixteenth century, say nearly during the last four hundred years, the bulk of the architecture of the civilised world has been Renaissance in style. When men feed upon a steady diet physically or mentally for twelve successive generations the race acquires a taste for it. Not because it has analysed its hygienic or intellectual properties, and has found them adapted to its physical or mental needs, but because the digestive apparatus has become incapable of assimilating other matters. Of course, you will tell me all about the revival of Mediæval architecture during the last half-century. You will point to the great achievements of Scott and Street, of Schmidt and Hansen, of Viollet-le-Duc and Gaertner and many others. You will speak of the restoration of the cathedrals, of Munich, the modern Romanesque city, of the Gothic work done in London and Vienna, and even in America, but I will tell you that during all this last half-century the bulk of the architectural work done, say nine-tenths of it or more, has been Renaissance. The pioneers of the revival of Mediæval art are passing away one after another, and there are no successors to fill their places mainly because the movement has not been a popular success. As for myself, I prefer to rely upon the great majority for a supply of clients, and, as clients go, they pay well, and are not exacting, provided you humour their notions and recognise their good taste, and that is only human nature after all."

Thus speaks the architect of fashion, and thus he acts. It is desirable to know what becomes of architecture under his management, and incidentally how it affects the architect. To dispose of the latter first in as few words as possible, it seems clear that the architect is rapidly descending from his high professional position and ranging himself with that class of mercantile enterprise which, having no confidence in intrinsic merit and real usefulness to society, seeks recognition by drumming and advertising. The lawyer, physician, clergyman, engineer—yes, even the mason, carpenter and horseshoer—claim to have acquired a knowledge of the theory and practice of their respective vocations which is not shared by the public, and tacitly deny the right of their clients to decide upon the methods and means to be used in carrying out the work entrusted to them.

The architect of fashion defines his position somewhat as follows:—"Architecture," he says, "is a science as far as it relates to mere building, and an art in clothing the building in certain forms. The latter is a matter of taste, and the architect being an artist is presumably possessed of a large share of this taste, but inasmuch as the forms of architectural monuments are determined for us by architects of past periods, and cannot now be changed, and as furthermore our clients have a preference for certain architectural styles, it is but reasonable to admit public taste as co-ordinate with that of the architect."

There are those who assert that there is a logical relation between construction and the development of form, which is

not a mere matter of taste or convention, but one of scientific demonstration. But the moment the architect of fashion admits this argument he practically denies his client's influence in the premises, and risks the loss of his patronage. By ranging on the side of the public clients are prepossessed in his favour, and the number of his competitors is reduced to those who prefer business to professional convictions.

When to the architect is given the privilege of exhibiting his work on the corners of streets, on the highways and public places of the world, he can well afford to wait for recognition of his merit without advertising or personal drumming, unless indeed he has lost faith in his own work or in the intelligence of the public.

The architect of fashion has lost faith in the intelligence of the public. "They don't like Shakespeare," he says, "so I give them variations upon 'Potter of Texas'—variations because they don't like 'Potter of Texas' pure and simple for any length of time. They want something new—some marked change; but the change again must be in the style of 'Potter of Texas.'" So last year we had the Italian Renaissance, with a decided feeling of the Colonial. What is the Colonial? Why the carpenter's interpretation of the Renaissance as expressed in wood during the seventeenth and eighteenth centuries, delicate mouldings hardly practicable in stone, decorations and carvings with just a touch of relief, for in the Colonial times much of this work was done in putty. It takes very well, for most people hate things decided either in form or colour. Still they got tired of it, so this year they longed for something vigorous, and we treat the lower storeys of our buildings with aggressive rudeness, rough stone ashlar, small openings, great iron gratings in front of them and above we continue with the Colonial Renaissance. The contrast is striking. Next year, no doubt, we will have to go in for the Rococo, the latest phase of the Renaissance in France and Germany. It is elaborate, and doubtless will take on that account. Yet some of our most fashionable architects are of opinion that the early Renaissance of the Italian school, plain walls, bulged ashlar, openings far apart, small and plain in treatment, will be the leading style. They say that Boston is already prepared for it, and if it succeeds there Chicago is sure to follow. New York, however, is more conservative. There is a strong talk here of a return to the Grecian of the Treasury Building and the Custom House (the old Merchants' Exchange in Wall Street), and if that tide sets in in time, it may save that building from being demolished. Queen Anne, it is now agreed, is dead, and past the possibility of another revival.

Bold innovations, such as piling up quarry-faced stone, grotto fashion, exaggerated by pitching off the edges so as to produce a projection from the bed of 6 or 8 inches, huge arches with immense vousoirs, and no abutment to mention, enormous entrance doors extending to the full height of the building, are striking features of no artistic merit, quickly appreciated and admired and as quickly cast aside. Thus the architect of fashion maintains a well-stocked repertory of striking architectural forms; striking, because most frequently gathered from periods of architectural decay, and also of heterogeneous building material, loud in colour and contrast and peculiar in form and texture. From these he compounds combinations which constitute the fashion of the day.

Considered from a business point of view it saves much time. Once the leading draughtsman of the office is informed of the annual change, office work takes care of itself.

The old method of spending weeks and months in designing in the seclusion of one's library is utterly impracticable with the modern business habits of the architect of fashion. Two or three hours in the morning must suffice for office work, which consists mainly in receiving prospective clients, in brief and rapid interviews with clerks of the works, in signing certificates for payments to builders and dictating a few letters generally directed to hurrying delinquent work, for the architect of fashion must maintain a high reputation for doing work promptly and rapidly. The afternoons and evenings are devoted to social intercourse with probable clients who are visited at their offices, met on 'Change, in banks and insurance buildings, and later at clubs, receptions and public meetings.

The architect of fashion is ubiquitous. His problem is to procure new orders—jobs, as he calls them—and to this he devotes all his time and energies.

Now, let us turn to architecture to see how she fares under the rule of the fashionable architect. Architecture has ceased to be an art and has become a business, a fashionable business carried on by business methods on business principles.

The chief of the business, the architect, no longer pretends to be a man of learning, of varied attainments, of a liberal education, of studious habits, retiring, modest, shrinking from contact with the world, devoted solely to his art. No, he is a man of business, a man who startles the world by his bold combinations of architectural *bric-à-brac*.

It is said of Worth, the great French artist in female garments, that he will contract to make a fine dress for a few hundred francs, but for a few thousands he will produce what

he calls a dream. The fashionable architect also deals in dreams in architectural inspirations, combinations of fancy: hence he is a genius, too, a genius *à la mode*, like Worth.

Art, in the general acceptance of the term, is the skill (technical knowledge and mechanical facility, the results of study and practice) by means of which man is enabled to create organisms or represent them in matter in imitation of nature. Fine art means the creation or representation in matter of organisms which express an idea.

Raphael's *Madonna*, Thorwaldsen's *Apostles*, Dante's "Inferno," the cathedrals of the thirteenth century, Bach's oratorios—all these are works of fine art. They express in painting, sculpture, music, poetry and architecture the Christian idea of religion. Similar instances may be cited of the various fine arts of Greece and Rome.

It is not fine art to copy any one of these works, or to combine parts of them into one whole. For instance, a series of quotations from various poets, though it may bear upon the expression of an idea and may even be a meritorious literary effort, is not a work of fine art. The same applies to architecture. To copy a building or to combine features of various buildings, no matter how meritorious the originals, is not in any sense a work of fine art.

The fashionable architect not only copies buildings as a whole, which, by the way, is not the worst of his sins, but he combines features of various buildings into what he calls a design. More than this, he decides beforehand what particular features he intends to combine for the next year or two for use in all buildings, without reference to their nature or materials. Theatres, academies, club-houses and banks are all built after these models of fashion.

For instance, during the fifteenth and early in the sixteenth century the palaces of Florence, like the Strozzi, Riccardi, Ruccellai and others, had high basements above the street level devoted to domestic offices and servants' quarters, which basements were lighted on the street with small square windows, the sills of which are from 8 to 16 feet above the floor.

Now there was a very good reason for this. The feuds and factions of families were very warm in Florence in those days, and the palaces had to be fortified against popular risings. No such necessity exists with us at the present time, yet we see many specimens of basements of the kind, of which the small windows are besides protected on the outside with heavy iron gratings.

The portico of the Greek temple consists of columns supporting an entablature and cornice, upon which rests the gable or pediment. The cornice is the covering of the structure, its protection against the weather, hence its projection. The entablature is the lintel which sustains the cornice and the superincumbent pediment between the columns. If for the colonnade we substitute a wall the entablature becomes superfluous, and the magnitude of the cornice, although accepted as proper in a temple and perhaps also in a palace, should doubtless be reduced in secular structures, both in height and in projection. We observe this to be the case not only in the earliest Roman domestic structures, but also in the basilicas. Renaissance architecture, as derived from Vitruvius and his expounders of the fifteenth century, maintains the cornice and entablature as an indivisible whole whether sustained at intervals or continuously by a wall and by columns. Moreover, this crowning feature is introduced at every storey, with a full projection of cornice, as though it were the top of the building.

The architect of fashion accepts these forms as of good authority, and adopts them in his combinations. More than this, he is swayed by motives of habit, otherwise tending in opposite directions. During what is termed the Colonial period, cornices and entablatures were made of wood, and attenuated accordingly. The subsequent invention of the zinc cornice enabled ambitious architects to indulge in exaggerated cornices at a moderate cost. The architect of fashion builds his cornices of stone, but vacillates between the meagre Colonial and the exuberant zinc in their form and magnitudes.

TESSERÆ.

Landscape Sketching.

IN the selection of a subject from nature, the student should ever keep in view the principal object which induced him to make the sketch; whether it be mountains, castles, groups of trees, cornfield, river scene or any other object, the prominence of this leading feature in the piece should be duly supported throughout; the character of the picture should be derived from it; every other object introduced should be subservient to it, and the attraction of the one should be the attraction of the whole. The union of too great a variety of parts tends to destroy, or at least to weaken, the predominance of that which ought to be the principal in the composition, and which the student, when he comes to the colouring, should be careful to

characterise by throwing upon it the strongest light. In his attention to this rule, however, the student must be particular not to fall into the opposite extreme, by suffering the leading object of his composition so fully to engross his attention as to render him neglectful of the inferior parts. Because they are not to be exalted into principals it does not follow that they are to be degraded into superfluities. All the lights in a picture should be composed of warm tints, except they fall on a glossy or reflective surface, such as laurel leaves, glazed utensils, &c., which should be cool and the lights small, to give them a sparkling appearance; but care must be taken not to introduce a cold colour in the principal light, which, as already mentioned, should be thrown upon the leading feature of a picture, as it conduces to destroy the breadth that should be preserved, while, on the contrary, the opposition or proximity of a cool to a warm colour assists greatly in giving brilliancy to the lights. If the picture, for instance, should have a cool sky, the landscape ought to be principally composed of warm tints, as contrast of this description tends to the essential improvement of the general effect. All objects which are not in character with the scenes should be most carefully avoided, as the introduction of any unnecessary object is sure to be attended with injurious consequences. This must prove the necessity of becoming thoroughly acquainted with, and obtaining a proper feeling of, the subject. The picture should be complete and perfect in the mind, before it is even traced upon the canvas. Such force and expression should be displayed as would render the effect at the first glance intelligible to the observer. Merely to paint is not enough, for where no interest is felt nothing can be more natural than that none should be conveyed. Finally, it may be observed that it is only by a due attention to each distinct part and by a skilful combination of all that the whole can be effective and delightful.

Palladio's Buildings.

Palladio's buildings in Vicenza are in general very beautiful, but most of them are in a very forlorn condition. The fronts and even the columns are of brick, the entablatures of wood; and the stucco, with which both have been covered, is peeling off, but the circumstance does not diminish the merit of the architect, though it does the magnificence of the city. Palladio's columns are mostly mere ornaments; but in contemplating his buildings, it is impossible to feel this to be a fault. The sculpture which loads the pediments of the windows is certainly ill-placed; and still worse is the little panel of bas-relief so frequently introduced over the lower windows, dividing what ought to be one solid mass into two miserably weak arches. What is it then that pleases so much, and so universally, in the works of this artist? It seems to consist entirely in a certain justness of proportion, with which he has distributed all the parts of his architecture, the basement being neither too high nor too low for the order above it; the windows of the right size and well spaced, and all the parts and proportions suited to one another. The same excellence is found in his orders, and the relation of the columns, capitals, entablatures, &c. He has not adopted the theoretical rules of another, but has drawn them all from what he felt to be pleasing to himself and suited to his own style of art; but they are not good, when united to a more solid and less ornamental manner.

Roman Discharging Arches.

The Romans appear to have been early accustomed to the use of discharging arches; they introduced straight arches (that is, an arrangement of bricks acting against one another as wedges, but kept in a line nearly or quite straight) over their openings instead of solid stone lintels, but aware of the weakness arising from this method of employing the materials they formed over them a semicircular arch, by which means the weight of the superincumbent wall was thrown upon solid parts which were able to bear it. In the earliest buildings which remain, and in general, even down to the time of Caracalla, this practice was used reasonably; and with moderation, but in later times arches were employed, not for use but for affectation; straight arches were employed where there were no openings, and discharging arches, which threw the weight rather on a weaker than on a stronger part.

The Gol Goomuz, Beejapore.

The tomb of Mohammed (the Gol Goomuz), Beejapore, consists of a square apartment, measuring 135 feet each way. At the height of 57 feet from the floor line it begins to contract by an arrangement of pendentives, as ingenious as beautiful, to a circular opening of 97 feet. On the platform over the pendentives is erected a dome, semi-elliptical in outline but circular in plan, 124 feet in diameter, leaving a gallery more than 12 feet wide all round. The internal height of the dome is 175 feet, the exterior to the apex 198 feet; the general thickness is about 10 feet. At the apex, however, it is nearly 18 feet; yet, if the tradition of the place can be depended upon, it was built wholly without centering. The most ingenious and novel part of the construction of the dome is the mode in which the lateral thrust is counteracted. In the

Pantheon, and in European domes generally, this is counterbalanced by a mass of masonry in the haunches, as is also the case in bridges. This mass, however, entirely destroys the outline, and is, to say the least of it, a very clumsy piece of masonry. Here the object is accomplished by hanging the weight inside: the massive pendentives having a tendency to fall inwards act as ties, and effectually accomplish the object without the possibility of derangement to the structure, as from their arch form they are perfectly stable in themselves. The external ordinance of the building is as beautiful as the internal. At each angle there is an octagonal tower of eight storeys, simple and bold in its proportions, and crowned by a dome of great elegance. The lower part of each face is plain and simple, pierced only with such openings as are requisite to admit air and light in that climate, and they are not a tenth of what would be required in ours. At the height of 83 feet a cornice projects to the extent of 12 feet, nearly double what the boldest European architect ever attempted, and above that an open gallery gives lightness and grace to the whole structure. Above the gallery is an ornamented band of fretwork, which is surmounted by a battlement of great beauty, relieved by eight smaller minarets, two on each face. On comparing this with other domes, it will be seen that it is the first in area. It covers more ground clear of support than any dome or vaulted roof in the world, while it is of more difficult construction, being placed over a square hall instead of a circular drum. Considered, therefore, either as a mechanical or as an artistic form it must rank among the first, if, in fact, it be not the most beautiful as well as the largest domical building, yet erected in any part of the world. The diameter of the Pantheon, Rome, is 142 feet; St. Peter's, 139 feet; St. Maria, Florence, 139 feet; tomb of Mohammed, Beejapore, 135 feet; St. Paul's, London, 112 feet; St. Sophia, Constantinople, 107 feet; church at Darmstadt, 105 feet. In the Pantheon the internal area of circle is 15,833 feet; the internal area with recesses, 19,086 feet; the whole area of building, 27,157 feet; the area of supports, 7,477 feet; the ratio of supports to area, 363 feet, while in the tomb of Mohammed the internal area of square is 18,360 feet; the internal area with recesses, 19,371 feet; the whole area of building, 24,964 feet; the area of supports, 5,593 feet; and the ratio of supports to area, 446 feet. The fact is the Indians knew so well the capabilities of domes that they could play with them and have no fear of their falling; we in Europe are afraid of them, and have never fairly tested their capabilities. Sir Christopher Wren shirked the question entirely by introducing a cone, constructively no doubt the best form for his purpose—artistically the worst, as he confessed by hiding it both internally and externally. Brunelleschi halved the difference, adopting a form slightly curved externally. The octagonal form of his plan rendered this tolerable, though not beautiful. For a circular dome it would be unbearable. Michel Angelo did better, and produced a bolder construction and a far more artistic form, and had he been able to secure his base constructively, without iron ties, his dome might have been eternal. Had either he or Wren known, for instance, of this Beejapore mode of placing a mass at the springing, sufficient by its inertia to resist any movement in the vault, and to convert all outward thrust into inward pressure, they might have constructed far larger domes far more solidly than they have done.

Perspective Drawings.

Laws of perspective are laws of nature. We only know what a building is by what we can see it to be. The geometrical elevation, section and plan of that building are merely the means by which a skilled person—a scientific person or an architect—is able to lay before the builder or the public the mode by means of which he intends to carry out his primitive idea, if it is an idea at all, of the building, the perspective effect of which he has in his mind. He must or ought to have imagined the building in perspective before he brought it upon paper. Architects' designs ought always, therefore, to be drawn in perspective. An architect, in fact, ought to think in perspective, and not think by the T-square and the drawing-board, for this is completely bringing down and reducing the function of the architect to the mere level of a simple geometrical transaction. It is not that. The architect conceives his building in his own mind first of all, but has to explain the way in which he wishes it to be executed so as to produce a certain effect upon the beholder, and that effect can only be understood and appreciated by the laws of perspective, and by the means which every person has of looking upon a building. It is undoubtedly right and just that the architect should give the idea as he originally conceived it. Some people may say that a perspective view does not give the original conception from more than one point of view out of a thousand; that is very true, and the more perspective views the artist can get the better for the purpose. There is another great objection to presenting a building solely in elevation, as it becomes difficult for even an architect to say what the effect of

certain projections will be. We know very well that every octagon put upon a square in geometrical elevation presents the same breadth from top to bottom. The moment we have it in perspective we see that the octagon is less than the square except from certain points of view; from the four cardinal points of view, if they may be called so, a very good geometrical elevation can be obtained, but from any other point of view you do not see that effect.

The First Exhibition of the Water-Colour Society.

The original projectors of the Society of Painters in Water-Colours held their first meeting at the house of Samuel Shelley, in George Street, Hanover Square, a miniature-painter of celebrity, and a protégé of Sir Joshua Reynolds. The parties were Shelley, Hills, Wells, Varley, Glover and Pyne. The outline of the plan being arranged and made known, some few names were added; subsequent meetings were held alternately at the residences of the aforementioned projectors, when it was at length resolved to form a society for the purpose of establishing an annual exhibition composed of original subjects, painted in water-colours, exclusively the works of its members. The first exhibition was opened to the public on April 22, 1805, at the Great Room, in Lower Brook Street, Grosvenor Square, which was built by Vander Gucht, an engraver, who, quitting that art, became eminent as a dealer in pictures. He was succeeded by his son, in the same business. The premises, after the decease of this gentleman, who was much esteemed both by dilettanti and artists, were occupied by Thomas Barker, of Bath, celebrated for his picture of *The Woodman*, who in the Great Room made a public exhibition of his own works. From Barker the premises were consigned to Tresham, who having little occasion for the Great Room let it, together with its appurtenances, to this Society, and therein appeared the first collection of works painted in water-colours, which could be seen to advantage and appreciated according to the merits of their respective authors. The following members contributed to the first exhibition:—G. Barrett, J. Cristall, W. S. Gilpin, J. Glover, W. Havell, R. Hills, J. Holworthy, J. C. Nattes, F. Nicholson, N. Pocock, W. H. Pyne, S. Rigaud, S. Shelley, J. Varley, C. Varley and W. F. Wells. No sooner was this novel exhibition announced than the members had reason to rejoice at the experiment. The room was crowded by the first personages, who appeared emulous to become purchasers of the works exhibited for sale. This successful commencement was greatly owing to a plan which had been suggested by a member and which had its desired effect, namely, that of having a person in the room who was furnished with a book containing the prices of each picture. Conditions of sale were also inserted, and the purchaser on entering his name therein advanced a deposit of 10 per cent. on the price affixed to each work, and bound himself to pay the remainder on delivery of each purchase. Hitherto very few instances could be named of the pictures of living artists being disposed of at a public exhibition, whilst here the room at once became an excellent mart for sale. The subsequent success which has continued to attend on their exhibitions, in the increase of patronage and other favourable circumstances, is an existing proof of the good sense and foresight which dictated the measure.

Points of Support.

He is the ablest constructor who, with the least surface to his points of support, upholds the greatest weight uniting strength and economy. The freemasons of the Middle Ages have established the principle of construction that, with equal quantities of material, a thin wall with buttresses has greater strength and stability than a thicker wall without. Piers with equal superficies of base, as a circle, a square, an equilateral and a right-angled triangle, have the following strength approximately:—100, 93½, 86 and 76½. A square is to a parallelogram as 100 : 95. The strength of a wall depends rather upon its stability than upon the greater or less hardness of the materials. The stability of solids diminishes in proportion to the height of the centre of gravity.

Architect's Estimates.

It is one of the morals of architecture that the architect should never lead his employer into a useless expense, nor into one which his means would not enable him to afford. It is a breach of integrity which nothing can render excusable. Vitruvius records a wise law of the Ephesians. When an architect was employed upon a public work, he was required to declare the amount it would cost, and his goods were made over to the State. If the work cost one-fourth more than his estimate, it was allowed; if it were less, he was loaded with honours. But if the expenditure exceeded the prescribed limits his property was sacrificed to make good the deficiency. It is said that Vanvitelli, having exceeded his estimate in a public work connected with the execution of one of the fountains of Rome, was mulcted in the sum of 5,000 crowns.

NOTES AND COMMENTS.

WE suppose it was to be expected that the Corporation of Manchester and the directors of the Ship Canal could not long co-operate without a breach. The short experience of the working of the canal can hardly be considered as warranting a belief that it will soon be as profitable an enterprise as was anticipated. The people of Manchester might be able to wait patiently for a few years without high dividends, but what is hard to endure is the prospect of having to contribute still larger sums of money before the canal can be considered as capable of meeting all kinds of traffic. The advances to the canal company will shortly require the imposition of a rate of about 1s. 8d. in the pound, and if more money is given the rate will have to be increased. When it was first proposed that the Corporation should come to the rescue, a sum of less than a million was supposed to be enough to enable the company to overcome financial difficulties. Afterwards the Chairman formally put down the amount at 1,700,000*l.*, and it was stated that "this apparent deficit is mainly due to the lock-up of the plant and other assets which cannot be realised until the canal is completed." The Corporation, before obtaining powers to make the advances, obtained an independent estimate, and it was then found that the amount rose to 2,313,173*l.*, including 15 per cent. for contingencies. On that basis an Act was obtained. It was soon found that the cost of the work to be done was underestimated. Another estimate increased the amount by 863,595*l.* But the data for several items was incorrect. For instance, "dock equipment sheds, &c.," was put down at 90,000*l.* But that one item has already cost 279,390*l.*, and a further outlay of 168,000*l.* is absolutely essential. There was another item of 5,500*l.* to reinstate a chemical manufactory near Runcorn. The expenditure has been 80,000*l.* Coaling ships which were to cost 10,000*l.* have already cost 46,000*l.*, and will still need 10,000*l.* A diversion of a stream was estimated at 2,500*l.*; the outlay will be 22,000*l.* For dredging an approach at Eastham the estimate was 36,000*l.*, and the expenditure 76,000*l.* From the Corporation or taxpayers' standpoint the obligations incurred by the company are more grievous, for the fulfilment of them would nearly exhaust the municipal resources. It is the unknown liabilities which are most to be feared, and it would be absurd for Manchester to allow itself to be converted into "the predominating partner" without having proportionate control of the undertaking.

THE Parisian amateurs are rather chary about forming costly collections of paintings; still there are a few in Paris and the neighbourhood of the city. The *Figaro* has drawn attention to the most important. First comes the collection of the Duc D'AUMALE, which eventually will pass into the possession of the State. It contains RAPHAEL'S *Three Graces*, for which 25,000*l.* was paid, and his *Madonna of Orleans*, which cost 6,000*l.* In Paris the collection of M. CHAUCHARD, one of the owners of the drapery shops known as the Louvre, is pre-eminent, for it is worth about a million sterling. Among the contents are MILLET'S *Angelus*, which cost 30,000*l.* In Baron ALPHONSE ROTHSCHILD'S gallery is RAPHAEL'S *Cesar Borgia*, from the Borghese collection, which cost 600,000 frs. Baron GUSTAVE ROTHSCHILD possesses MEISSONIER'S *A Reading at Diderot's*, which is supposed to be worth a similar sum. Two works by REMBRANDT in Baron EDMUND ROTHSCHILD'S collection cost 750,000 frs. Into whose possession RAPHAEL'S *Violin Player* has passed is not mentioned by the *Figaro*. M. MARIUS BIANCHI can enjoy the sight of twenty paintings by MEISSONIER. The *Bowlers*, by the same artist, belongs to the Marquis DE CASA RIERA, and the "1814" to the Duc DE MORNAY. M. BISCHOFFSHEIM possesses *A Country Dance* by WATTEAU, for which 10,000*l.* was paid. M. ROUART owns over sixty pictures by COROT. M. BOUCHERON, the jeweller, has given the preference to COROT, FROMENTIN and ROUSSEAU. For examples of MANET'S Impressionist experiments there is no collection so rich as M. FAURES', and the Marquis DE BIRON has accumulated pastels of the eighteenth century. The importance of the private collections will appear greater if compared with the few which existed in Paris fifty years ago.

THE Burgh Police (Scotland) Act of 1892 will have an important effect on the utilisation of sites for buildings. It will no longer be possible for an owner to dispose of his own land as he may desire. An example of the change which has taken place was afforded a few days ago in Paisley. A grocer proposed to take down two houses, and on the site to erect a four-storey tenement house. Application was made in the Dean of Guild Court for approval of the plans. The Master of Works objected because the stipulations of the new Act were not observed, for three-fourths of the area must be free as an open space. The applicant's lawyer argued that the clause was vague and misleading, for it stated that the three-fourths air space behind a property should be "attached thereto," but did not state that the space behind should belong to the proprietor of the building. There might be plenty of air space, he said, behind a tenement, and yet all the ground might not belong to the same proprietor. It was also contended that a distinction should be drawn between buildings to be erected on a new line of street and the taking down and re-erecting of properties on existing sites. The Court was not to be persuaded that the Legislature did not contemplate dealing with each site by itself. The application was accordingly refused. It will therefore be necessary to modify the plans considerably, and to contemplate the erection of a much smaller house.

THE ratepayers are likely to have to face a new and costly series of alterations in the London Board Schools. The Hackney divisional members recently recommended that the hall in one of the schools at Haggerston should be made suitable for holding public meetings, and for the assembling and drilling of the children. The architect visited the building and applied tests. He found that with a class of forty-five children placed four abreast in the centre of the hall (and with the ordinary drill), there was found to be a considerable amount of vibration, and with a class of sixty-five children similarly placed and brought close together, the vibration was very noticeable. Under the dance-step the floors deflected about an inch when the spring for final step was taken. The mistress stated that the vibration prevented her from writing at her desk in the hall when the children were walking in step from one classroom across the hall to another. As the introduction of an occasional steel joist would not give the desired stiffness the architect recommended the reconstruction of the floor in iron and concrete with a wood-block covering. The cost is estimated at 480*l.* What is necessary in Haggerston is likely to be carried out elsewhere, and it may therefore be assumed that an expenditure of 500*l.* per school for new flooring in the halls will be comprised among the numerous "repairs" or transformations which are comprised in the budgets of the London School Board.

THE Municipal Council of Paris deserve credit for perseverance in setting up plaques which will enable citizens as well as strangers to identify houses which are associated with celebrities. The latest cases are the following:—No. 29 Rue Etienne Marcel, which is connected with the history of the French drama for over two centuries. It was there the Confraternity of the Passion performed mysteries, and where the Sans Souci troupe, the comedians of the Hôtel de Bourgogne, the Italian Comedy and the Opéra Comique afterwards exemplified different forms of acting in the period between 1547 and 1783. The other houses were also occupied by men or women who in various ways were connected with the stage. GRÉTRY, the composer, occupied part of No. 9 Boulevard des Italiens; in No. 32 Rue St. Denis EUGENE SCRIBE, the prolific dramatist, was born; HONORÉ DE BALZAC, who was far less successful with his dramas than with his novels, died in the house at the junction of the Faubourg St. Honoré with the street now called Rue de Balzac; ALFRED DE MUSSET, whose "Proverbes" are still employed as curtain-raisers, was born in No. 33 Rue des Roys; finally, SOPHIE GERMAIN, the actress, died at No. 13 Rue de Savoie. When may we expect to see the London County Council placing commemorative plaques on houses in the Metropolis which have gained "betterment" by the residence of men and women who are worth remembrance?

EGYPTIAN DECORATIVE ART.

IN his third lecture before the Royal Institution on "Egyptian Art and Decoration," Dr. W. Flinders Petrie said that in the persistence of certain forms which were the direct result of the structure of a building or object we have a very considerable source of decoration. In Greek architecture many details are entirely the product of wooden construction translated into stone. The triglyphs, the imitations of nail heads, and of the ends of the poles supporting the roof, are details retained as decoration long after they ceased to have any structural meaning, owing to an entire change of material. Such is structural decoration in its best-known form. But the same principles equally apply to Egyptian architecture where the original material was the papyrus and palm branch with mud plastering and mud bricks; and the details of the stone architecture have come down from this stage translated into stone, as the Greek translated his into marble. But pottery preceded stone in Egypt, giving rise to one of the simplest ornaments. In the Egyptian yards still may be seen bowls and jars held together by a twist of rough palm fibre cord, while they dry in the sun before baking. This marking is to be seen on the pottery of all ages; but it was developed as a pattern in the twist or *guilloche*, probably rather derived from this than from the chain of coils or wave pattern. Basketwork was elaborately developed in the old kingdom. There are beautiful screens behind the figures of the owners of the early tombs; these in some cases might represent matting, but others appear to be of a rigid material. In no case were they "mats on which the kings stand," as styled by Owen Jones. Among the squares, waves, zigzags, chequers, &c., some are made by binding the fibres into bundles, which may have led to the common pattern of connected rhombs. Wooden framing is one of the most familiar early motives, and it is frequently imitated in the stone figures of doorways in the tombs, showing that a lattice frame must have been used in former times, as it is now, to admit light and air while the doors of the house were fastened. The same style was used in the upper portion of the dwelling with decorative uprights of the hieroglyph *tat*, and was copied as a fancy decoration in furniture, as shown in a beautiful ivory carving in the Louvre. This style survived till the eighteenth dynasty, and is seen in a tomb at Thebes. Akin to this is the panelling of the brickwork, identical with that of walls in early Babylonia, an indication of the common civilisation of the two great valleys. A well-known characteristic of Egyptian architecture is the sloping faces of the walls and pylons. To give more cohesion to a wall it was built on a curved bed, so that the courses all sloped up outwards at the outer corners, and the outer faces sloping inwards, the wall had more stability. This was copied in stone at the earliest time. The temple of Senefru, at Medum, has a slope on the face of about 1 in 16, and this custom continued down to the very latest age of Roman building. Another familiar feature is the roll or torus, down the corners of the building, usually ornamented by a pattern of binding. As Professor Conway has well pointed out, this was evidently a bundle of reeds bound together and put down the angle of the plastering to preserve it from breaking away; ugly at first, but copied in stone as a decoration for 4,000 years, as long as Egyptian architecture lasted. The European habit of seeing a hidden sense in every flower was not akin to the simple and elementary Egyptian. But he used certain striking emblems, one of the earliest being the uræus snake or cobra, in his wrath, reared with expanded body, ready to strike. The dignity and power of the animal made it an emblem of the king, or rather of the royal power of death. The Westcar Tales show that capital punishment was in use in Egypt, where in the old kingdom a condemned malefactor is ordered forth for a magician to try his power in bringing him to life when slain. The uræus was on the head-dress of the king, and from the earliest days (at Medum) the court had a cornice of uræi. In later times it was used on any royal structure. Connected with this symbolism is that of the globe and wings, dating from the beginning of the monumental age, and is seen above the figure of Khufu seated before a table of offerings, on an amulet, although the scale is

too small to show the details. What its symbolism was we do not know, but as the spread wings are those of the vulture, it seems to present the same idea—the power of life and death. But it is Ra who wields this power, and that the wings give the meaning of protection is shown by their embracing the royal name and guarding the king. The vulture alone as the emblem of protection is frequently figured with outstretched wings across ceilings and passages of royal tombs. The imposing sight of this bird, with its wings stretched at a span of about 19 feet, hanging close overhead, must have always excited the admiration of men. The scarab was another typical animal, rolling the pellet containing an egg to a safe place, where it buries it. Though very common as an amulet for the king and the dead, it is not often seen in symbolical or decorative use otherwise. It is often figured as holding the disc of the sun in its claws, and it is possible that the symbolism arose from the burial of its ball being an emblem of the setting of the sun to rise again to new life. The lion frequently figures in the eighteenth dynasty. The Egyptians had a marvellous instinct for taming animals, and trained lions or leopards to live domesticated like modern hunting dogs. The lion went to battle with the king, but in camp lay down as peaceable as an ox. It was frequently carved on the sides of thrones of the eighteenth and twentieth dynasties, and also seated in pairs, facing or backing on the temple walls, a usage recalling the lion gate of Mycenæ of the same age. Some Egyptian divinities appear as ornaments, such as the goddess Uaat, Hathor and Bes, who was one of the favourite popular deities. The little statuette of a dancing-girl with a Bes mask found at Kalmu shows his popularity in the twelfth dynasty. At Tel-el-Amarna ornaments for necklaces in glazed pottery show him dancing with a tambourine and with arms a-kinbo, and in the Roman age he is seen in the dies above the columns at Denderah in the temple of the Mammeisi. The hieroglyphic signs also served for symbolic decorations, as the Egyptian mode of writing could by a single mark express an abstract idea, and this has been done even in alphabetic characters, as in the elaborate crossing patterns of the earlier Arab period in Egypt. Four hieroglyphs are the most usual—the *ankh*, a girdle, symbol of life; the *hat*, possibly a feminine girdle, and always identified with Isis; the *was*, a stick of authority, and the *dad*, a row of columns, symbol of stability. The *sam*, or symbol of unity, is also used, and it is plainly a column of some kind, with a well-marked capital and an abacus. Another design came into fashion during the great foreign wars of the eighteenth dynasty, representing two captives, one negro and one Syrian, bound back to back against the *sam*; thus it symbolised not only the union of Upper and Lower Egypt, but also of the northern and southern races outside of Egypt, and later on we find four or even six such racial types figured as bound together.

ROMAN PALACES.

TO an architect, the modern palaces of Rome are invaluable as a collection of experiments on architectural beauty on a grand scale and in a grand style, for however they may be abused as extravagant, absurd or preposterous, they at least avoid the greatest fault that a building can have, that of being mean and paltry. The Romans, even in these their degenerate days, have adopted a style fit for those who had the world at their command. These palaces are rarely decorated either with columns or pilasters, and they are better without them, for these never look well in a building of many storeys in height. Ornaments round the windows are never omitted, and never should be omitted, for without them a window is a mere hole in the wall. The Roman architects have more often erred in making these dressings, as they are called, too large than too small, and their details are frequently very bad; yet even in their worst state they contribute greatly to the general beauty of a building, much more so when they are well designed. The storeys are generally divided by horizontal bands or mouldings along the front, and great space is left between the ranges of windows. This latter circumstance is of great importance. It gives an air of solidity and magnificence to the front, and suggests the idea of lofty rooms within, and it is a great point gained when, in addition to the magnificence which is seen, the artist can excite the idea of other magnificence which is not seen. This space is, however, sometimes broken by a disagreeable mezzanine. The whole is crowned by a large and rich cornice. The perfect beau-ideal of such an arrangement is not to be found in Rome, although some of its palaces are highly beautiful, but it cannot fail to be excited in the mind of an architect who attentively studies them. The body of the edifice is nothing but a useful dwelling-house, the ornaments naturally arise out of the construction required for such an object, and the design is capable of any degree of magnificence suited to the rank and consequence of the owner. In short, we find in it everything which can satisfy the eye, the imagination and the judgment.

CANALETTO AND VENICE.

WE publish this week reproductions of two of Antonio Visentini's engravings after paintings by Canaletto, from M. Moureau's "Antonio Canal" (Paris: Librairie de l'Art), a work which was noticed in a late number. The two subjects, like most others in *la Città d'oro*, are not strange to our readers, for, as Valery says, "the paintings of Canaletto have so familiarised us with the harbour, the squares and monuments of Venice, that when we penetrate into the city itself, it appears as if already known to us."

international resort is less evident than in Valery's time, when it was without a rival. "The East and the West," he continues, "are there brought into each other's presence. There are Turks, Greeks and Armenians, some lying down, others taking coffee and sherbet, under large awnings of different brilliant colours, resembling tents; some smoking perfumes in their long amber-tipped pipes of rosewood, a crowd of indolent and majestic automata, while European travellers and others, occupied with their business, are hurriedly passing to and fro."

At the top of the Piazza are to be seen the basilica of St.

THE PIAZZA, ST. MARK'S

By Canaletto,

One of the plates represents the famous Place, or Piazza, which in Canaletto's time was enlivened by a greater variety of costumes than he introduced. In the early part of the present century Valery could say, "Venice still palpitates on the Piazza of St. Mark; while other quarters possessing magnificent palaces are allowed to fall into ruins, a million of francs are expended yearly in upholding the Piazza. The corpse of a city, to employ the expression of Cicero's friend, is already cold at its extremities; the life and heat which remain are confined to the heart." At the present time there are occasional signs of animation in the Piazza, but its character as an

Mark, the Campanile and the Ducal Palace. Not unworthy of such companionship are the three bronze pedestals modelled by Leopardi for the masts which sustained the standards. The row of buildings on the left, or northern side, dates from the end of the fifteenth century, and was designed by Bartolommeo Buono, who completed the Campanile. The row on the right side is by Scamozzi. But almost as much credit must be assigned to Sansovino, for the lower arcades and those of the first floor were determined by the adjoining Biblioteca Vecchia, the building which, through the collapse of a ceiling, brought Sansovino into disgrace, and caused him

to be punished by fine and imprisonment. Palladio considered the Library to be the richest and most ornamented building that had been constructed since the times of the ancients. It was employed by Smirke as the *motif* for the Carlton Club in Pall Mall.

In the quay view we again see parts of St. Mark's, the Palace, the public clock, and the Campanile. There are also the Piazzetta, leading from the Piazza, with the columns of St. Theodore and the Lion of St. Mark, a façade of Sansovino's Library, his Zecca or Mint, and on the other side of the Palace is the Prison. Canaletto cared only for exterior views, and as

overhauled, it was accepted as remaining unchanged. It was well old Howell's criticism was not known in Venice, for to say, "I believe there is not a foot of that timber remaining which it had upon the first dock, having been, as they tell me, so often planked, ribbed, caulked and pierced," was a crime that was enough to have a man conducted to the piombi or the pozzi.

The Bucentaur was about 100 feet long and 21 feet in width, and to move it 168 oarsmen were required, besides 40 sailors. The carving alone formed an immense weight, for the barge was covered with figures of marine deities, sirens, winged lions, allegorical figures, shells, medallions, and in fact everything

THE DUCAL PALACE AND THE "BUCENTAUR."

By Canaletto

the Quay and Piazzetta were his favourite resorts, he was glad to represent them as they appeared on Ascension Day, the great festival when the doge undertook an excursion in the Bucentaur or State galley, in order to wed the Adriatic. The origin of the name is doubtful, but whether the vessel was in any way suggested by a taurus or bull or a centaur, it was one of the most extraordinary examples of naval architecture. We speak of it as if a single Bucentaur existed during seven centuries, for by one of those fictions which are common in Government business, although the barge was always being

that could suggest the purpose of the structure or the greatness of the owners appears to have been introduced. The upper deck was covered with an awning of crimson velvet, beneath which the doge, senators, grantees and ambassadors were seated. The doge was enthroned in the stern, and the most distinguished guests were around him.

The excursion was intended to celebrate a victory obtained in 1177 by Doge Ziani over the Emperor Frederic Barbarossa. The Venetians were then upholding the cause of Pope Alexander III., who after the victory presented the doge with a

ring, saying, "Take this ring, and with it, on my authority, the sea as your subject. Every year you and your successors shall make known that by right of conquest the Adriatic has been made subject to you as a wife to her husband." Accordingly on Ascension Day the doge and his guests were rowed to the Lido, and at the mouth of the harbour he cast a ring into the Adriatic, uttering the formula, "With this ring we wed thee in token of our true and perpetual sovereignty." It was always understood that the water was cognisant of the honour of becoming the doge's bride, and dutifully remained in a placid condition during the ceremony. If there were matrimonial storms the captain paid the penalty.

The two illustrations will suggest the character of those in M. Moureau's book. They comprise the most characteristic examples of Canaletto's architectural views, and form one of the best memorials of Venice which the visitor can possess.

THE ASSOCIATION AND WORKSHOP PRACTICE.

THE following correspondence is found in the last number of the *A.A. Notes* :—

The Architectural Association, 56 Great Marlborough Street, W. : May 24, 1894.

Dear Ashbee,—The more I think over the scheme which we discussed when I visited you at the Guild, the more convinced I am that it is a practical one and calculated to benefit our A.A. students in exactly the manner which the best spirits amongst us have so long desired; I mean, of course, the placing within the reach of our students opportunities for gaining practical knowledge in the workshops as supplementary to the instruction given at the Association.

If this scheme is to be put forward during next session it would be necessary that some active steps should be taken at the earliest possible date, and with this view I am sending you a few proposals :—

1. That the A.A. students be drafted at the end of, say, their third year into a practical workshop, to get experience of its workings, to work out designs of their own and to learn the limitations of various materials by working with their own hands and to come into direct contact with the workmen.

2. That this should be arranged by a fixed charge of, say, seven guineas per student for the year.

3. That it form a definite continuation of Division III. or other divisions or classes in the A.A. curriculum.

4. That the above object be accomplished by affiliating to itself the workshops of the Guild and School of Handicraft. (See Brown Book, p. 187.)

5. Whether you as director of the Guild and School of Handicraft would be willing to enter into some provisional agreement with the view of carrying out the above proposals.

If you could let me have your views as to this scheme before Friday evening next I would lay it before the committee in order that time might be saved.

6. I should be very glad to know what you think we might do in order to make the financial side of the above scheme more possible.

Do you think the London County Council could be asked to assist in the form of scholarships to be held under certain conditions, say, ten or twelve scholarships of 10*l.* and one or more of 25*l.* for the best man?—Yours sincerely,

(Signed) F. T. W. GOLDSMITH, hon. sec.

Mr. C. R. Ashbee, M.A.

[COPY.]

Maggie and Stump House, 37 Cheyne Walk, Chelsea :

May 25, 1894.

Dear Goldsmith,—I am glad you think the scheme we discussed is a feasible one, and speaking provisionally, in reply to your letter of May 24 I am prepared provisionally to endorse it. Subject, however, to the following reservations and conditions, and if it would not be amiss, might I suggest it for you to add them to the clauses proposed in your letter?

In clause 2 I do not see how the scheme is financially possible at the rate of seven guineas per head, unless the freedom of the pupils as regards the workshop is curtailed, and the class system is introduced. We want your fellows to have the "run of the shop," plus "personal supervision and teaching" continually. We cannot do this unless there is a margin. Put the case thus :—If we took an ordinary "gentleman apprentice" into the shop we should require of him a premium of 30*l.* at least, then the value of his work, if any, at the end of his time, and his work would be of some value, as we should put him on to a definite line and be productive. To your men we propose to give the same advantages, but as the teaching is not with a view to direct production, there will be no productive gain. I fear, therefore, that you must regard 10*l.* as the minimum possible sum per head unless, as I say, the class system is introduced.

You might, therefore, add the following to your clauses (under clause 5) to which I provisionally agree :—

(a) That students shall have practical teaching from skilled artisans in the following subjects :—Ironwork, carpentry, joinery, wood-carving, hammered and chased metalwork, hollow-ware, work in precious metals, enamelling, leather-work, work for constructive purposes in wax, clay, plaster, and if circumstances permit, in stone masonry and carving. They could also have a special training in the drawing and measuring up of old buildings in our proposed London survey.

(b) That the teaching shall be conducted less in the form of classes (as is customary at technical schools) than by direct personal supervision from the artisans skilled in the different crafts above-mentioned.

(c) That as the object of the scheme is the application of design to material, it be considered an integral part of the scheme that the pupils bring their own designs for criticism and execution in the workshops.

(d) That the students shall be during their year of teaching considered as under my discipline and guidance, but that the whole course of study and its arrangement be under the direction and control of the A.A. general committee.

(e) That a minimum number of ten students be provided by the A.A., and the fee, 10*l.* per head, be paid collectively to the Guild and School of Handicraft in regular monthly or three-monthly instalments.

(f) That this sum include only such materials as shall be deemed necessary by the instructors at the Guild and School of Handicraft for the teaching proposed, but that either the A.A. or the individual pupils pay the cost of any material needful for carrying out special designs.

(g) I may add that the school or educational committee of the Guild and School of Handicraft would be willing, if necessary, to entertain the idea of co-opting on to it a representative of the A.A.

Your suggestion, sixth, as to the County Council, I think excellent, and I shall be glad to help you in that direction if I can.—I remain, yours truly,

(Signed) C. R. ASHBBE.

Mr. F. T. W. Goldsmith.

AN AMERICAN JUDGE ON ARCHITECTS' DUTIES.

THERE are occasionally grounds for complaining of the summary view which is taken in the courts when architects bring actions for the recovery of fees. As a contrast, the following charge delivered in the Supreme Judicial Court of the State of Maine on the case *Arthur Rotch and another v. Fry and another*. The *American Architect*, to which we are indebted for the report, describes it as "the best presentation ever made in a court of record in this country, and perhaps the best ever made anywhere, of the duties of an architect," and our readers who have had to appear in cases of the same description will agree the praise is merited :—

The plaintiffs are a firm of architects in the city of Boston, of long experience and skilled in the art of building. The defendants, the owners of a site for a house or a residence which they contemplated building, at Bar Harbour, applied to them and sought their services. They inquired of them their terms, and there was handed to them a schedule of prices. With that they appear to have been satisfied, and thereupon engaged them to perform the work, and, in the absence of any further stipulation or agreement between them, the law would imply a promise on their part to pay the prices there stipulated. So that, in this case, the prices which they would be required to pay, and which the plaintiffs are entitled to receive, are the prices given according to the schedule which was furnished to the defendants at the outset. So far they cover the services that were called for or were required. I do not understand that the learned counsellor for the defendants denies this. On the other hand, I understand him to admit that, if his clients are liable at all in this case, they are liable to pay for the services charged according to that schedule, less so much as shall be deducted therefrom on account of conditions that I may call your attention to hereafter.

It appears that the defendants carried to the plaintiffs' office some sort of a topographical sketch or plan of their house site. The plaintiffs did not visit the locality, and did not have an opportunity to examine the ground. I do not know that it appears in the case that they were requested so to do, or required so to do at any rate. I think there was some testimony on the part of some of the witnesses as to whether it would or would not be necessary. At any rate, the services were undertaken to be performed without visiting the locality, the plaintiffs being guided by such information as the defendants could give them and such information as the topographical sketches or plans would indicate. Some consideration arose as to whether or not the house should be built with a projection, or L, at right angles with the main structure, or whether

it should be built with a diagonal projection. You have heard the evidence in regard to that. The defendants contend that they allowed the plans to go on by reason of an assurance on the part of the plaintiffs as to the feasibility of the square or the projection at right angles, that they allowed them to go on by reason of the advice and assurance of the plaintiffs as to the cost and feasibility of it, and were guided wholly by their judgment.

The plaintiffs continued in the execution of the plans; they procured the details and perfected the entire set of plans. For some reason those plans were rejected by the defendants. The plaintiffs say that it was because they did not give the house sufficient size and capacity and arrangement to suit them, and that they preferred an entirely different house, a house of different dimensions and different architectural proportions. The defendants say it was because they found the plans impracticable, and that the arrangement of the plans called for so great an outlay that it rendered it too expensive for them to be carried out and adopted, and they say that that was on account of the mistake of the plaintiffs in not properly advising them and in deceiving them as to the practicability of the plans.

Now, gentlemen, in determining the rights of the parties it is well to consider what the legal duty of the plaintiffs was to the defendants. The architect is skilled in the art of building houses. Those who employ him have a right to his best judgment, to his skill, to his advice, to consultations with him and to his absolute fidelity and good faith, and when the architect has contributed these things to the person who employs him his duty has been fulfilled.

Now in this case if these plaintiffs, taking the description of the lot from the defendants, and believing it to be feasible and best to advise a house with a square L, and in good faith they did so, and the defendants accepted the advice and relying upon it allowed the plans to go on and be finished to the minutest detail, then, gentlemen, the defendants have had a service for which they must pay. But on the other hand, if the plaintiffs deceived the defendants, and did not give them good and faithful service and advice, but knowing and having knowledge sufficient to warn them that a house of that sort would be impracticable and too expensive to be built, and withheld that information from the defendants and concealed it from them, and of their own desire and motive went on and built this house, leaving the defendants to find it out when completed, then, gentlemen, they cannot recover.

So, then, the question comes as to the first charge in this writ of 150 dols. for the plans and specifications for the first house. As the house was not built, it does not come within the schedule of prices contained in the slip that was handed to the defendants, and, therefore, it is left to the law to determine what the compensation shall be. And in such cases the law says that the compensation shall be a reasonable compensation. I do not know that the defendants deny that 150 dollars would be a reasonable compensation for the services, if they are compelled to pay it. If the learned counsellor denies that fact he can say so now; but I do not understand that he denies the reasonableness of the charge, but rather that the charge is illegal and that they are not required to pay it at all. So, gentlemen, take that consideration, under the instruction which I have given you and say whether or not these plaintiffs, taking into account the information which was given them by the defendants, taking into account their instructions, taking into account the defendants' views about it, and say whether or not they served them faithfully, honestly, in the exercise of good judgment, without fraud or concealment, without any attempt to compel the defendants to pay for a set of plans and specifications for a house that they knew were impracticable, and could not be carried out without unreasonable expense, and if you find that the plaintiffs were faultless in that regard, if you find that they acted in good faith and gave the defendants their best advice as to construction, skill and service, the defendants having taken it and accepted it, why then, gentlemen, the defendants must pay them a reasonable compensation for their service, which is admitted to be 150 dols., otherwise the defendants are required to pay them nothing. This is wholly a question for you to determine. The first plans and specifications were rejected some time in the month of April. I think that one of the defendants says that then he had a conversation with the plaintiffs about building him another house, and that they expressed a desire to do so, and I think he stated that he should be very glad to have them do so, and thereupon the plans and specifications for a second house were undertaken by the plaintiffs and carried forward to completion. After the plans were made they were accepted by the defendants and appear to have been satisfactory to all parties, and the building was placed under contract with a builder, whose duty it was to build and construct the house according to the plans and specifications. To this contract these plaintiffs are not parties. They are simply the servants of the defendants. They are required to give them their service, to follow their directions and do whatever they should direct to have done. The defendants might discharge them at any moment, or they might allow them

to continue. The plaintiffs, not being parties to the contract between the builder and the defendants, are not held bound by that contract, except in a general way, except in particulars that may perhaps be material and which I will mention hereafter.

You will notice by the terms of the contract that, as fast as the work progressed, the bills were to be submitted to these plaintiffs, the architects, who were to approve them, and when they were approved they were payable, and I understand that they were promptly paid. I understand that the house was built and that the defendants paid for it—for every nail, scantling, board, brick and shingle; that they have paid for the painting and the decoration, and that it is their house. The plaintiffs in this case have contributed nothing except their personal services. The house was to be built upon the land of the defendants, and when the house was completed and they had paid for it—paid for the material and labour—it necessarily became their house, and they could not reject it if there were faults on the part of the architects. They would not be required to do so, because it would be unreasonable to hold that, if the architects had failed to perform their contract faithfully, the defendants would be obliged to allow their house, costing upward of thirty thousand dollars, to remain idle and vacant until a lawsuit could be determined. They were not required to do that, so they moved into the house, and the plaintiffs are entitled to recover the schedule price for their services in preparing the plans and specifications and in supervising or superintending the building of the house. The amounts charged are not denied to be the schedule prices for that work, including the bill for travelling expenses, so that you need have no trouble concerning the items of the plaintiffs' account. They are indivisible, and no special assessment is required by you touching them, except so far as deductions may or may not be made from them as required by the instructions which I am about to give you. In the main the house seems to have been completed as the defendants had wished and intended; but the defendants say that the plaintiffs wilfully departed from their instructions, and wilfully built and finished it contrary to their explicit directions. In the first place, the defendants say that they directed the trimmings of the house to be of a particular colour. The plaintiffs deny this. They say that it was indefinitely left to them to choose the colour that would match certain other parts of the house, and give to it a proper artistic appearance.

Now, gentlemen, that is a question of fact. If the defendants specifically and explicitly directed the plaintiffs to paint the trimmings of the house a particular colour, and the plaintiffs understood those directions, it was their duty to follow them. It is the owner and builder of a house who has the right to say what sort of a house will please him, and what sort of a house shall be built, so long as he is able and willing to pay the expense of building it. But the plaintiffs say that this was left indefinite, and that they had no express instructions to put on the colour which the defendants contend they had, and this the defendants deny. That, gentlemen, is a question of fact. Are you satisfied, from the evidence, that the defendants expressly ordered the plaintiffs to put a particular colour upon the trimmings of that house, as they say they did, or does the evidence fail to satisfy you of that fact? If you find that the plaintiffs had specific directions as to the colour which should be put upon the house and, notwithstanding that, wilfully violated those directions to please themselves, because they thought a different colour would be better, then, gentlemen, the plaintiffs are in fault, and the defendants, having changed the colour to suit themselves and paid therefor the sum of seventy-five dollars, have a right to charge that against the plaintiffs' bill. So that, in regard to that matter, if you find that the paint was put on there in disobedience of the defendants' orders by the plaintiffs, then you may deduct from the amount the plaintiffs are entitled to receive the cost of changing it. But, on the other hand, the plaintiffs may have had talk in regard to these colours, may have advised about it, may have held out various considerations, and the defendants may have thought about it, and if the plaintiffs did not understand that they had specific and explicit directions, but that they had only received advice and suggestions, and they in good faith followed out their own best judgment about it, without wilfully violating the orders of the defendants, why then, gentlemen, even though the colour did not please the defendants, it is no defence to this action, and they must fail so far as that part of the case is concerned.

In the next place, the defendants say that the plaintiffs constructed the sashes of the French windows in express violation of their orders and directions. Now, gentlemen, how was that? The plans definitely and distinctly show the kind of French windows that were to be built and furnished. You will have with you the plan. That shows that the windows originally put into the plan and into the blue prints were exactly the same kind of French windows that were put into the house by the plaintiffs. I do not think that either party questions that fact. But the defendants say that after the plans were

made, and while one of the plaintiffs was at Bar Harbour, they called his attention to certain sashes in another house and directed him to have their sashes made like those shown. The plaintiffs say they do not remember any conversation of that sort, but they may have been asked as to whether the windows would be like those or not, but they do not remember definitely about it.

Now, gentlemen, the same considerations come in here that came into the other case. It is always well for the owner of a house, in matters of this sort, where the contract and specifications are in writing, to bear in mind that the architect, likely enough, has many jobs on his hands and many buildings under his control and is very likely to forget and omit specific directions, and if he wishes his architect to make changes, it is always well, if he wishes to give specific directions and to hold the architect to them, to give them in writing. The owner is not required to do so, but it is well that he should. This was not done in this case, and you will determine whether or not the plaintiffs, in following out the plans that had been given them and putting in the windows exactly as the plans and drawings required, violated the express orders and directions of the defendants, or whether, in good faith, they followed out what they supposed were his wishes and directions as expressed in the plans, and had not in mind any specific directions more than mere conversation or inquiry about it. It is just the same in this as in regard to the paint. Now, the testimony is (and I think it is undisputed), that for the changes made in those window-sashes the defendants paid 65 dollars. Well, gentlemen, if that was paid on account of the plaintiffs' wilful disregard of the defendants' orders, it may be deducted from the account. But if it was only required to be paid because the plaintiffs made a mistake about it and they built the windows in good faith, that was all that they were required to do, and if the defendants saw fit to change them afterwards they must pay the expense of doing it.

Now there are two other considerations which are of the same character, the dormer windows and the dining-room. The blue prints, or the original plans of the house, call for dormer windows apparently to be 2 feet 11½ inches from the floor. That plan the defendants had had and accepted, and they had reason to expect that the windows would be built at that height. The contract contains in substance a permission on the part of the defendants that the architects may make some changes, as they may think desirable, in the construction of the house, and therefore even though the blue prints called for these windows to be built 2 feet 11½ inches apparently, yet in the absence of more specific instructions from the defendants, if they in good faith thought it advisable and best, in the exercise of their best judgment and discretion, to raise the window-sills 7½ inches, and they did so, then, gentlemen, that would not prevent their recovery in this case. But if, on the other hand, they had received instructions to make the windows low and, knowing of these instructions to make them low, they deliberately and purposely went to work and made them high for some particular reason of their own, then, gentlemen, they violated their duty. You will take into consideration the probabilities of the case; you will take into consideration the motives which the plaintiffs would or would not have in doing a thing of that sort. In answer to an inquiry of mine it was stated by one of the witnesses that there were no architectural reasons why the windows should be raised—that it was not necessary that they should be raised on account of any architectural defects. Consequently, if that was so, the plaintiffs would have no reason to raise them simply to give a better appearance to their own work.

Now the plaintiffs say that, although the blue prints call for the windows to be 2 feet 11½ inches, they received specific directions from the defendants to make the windows high, and that they thereupon, in making their frame-plans, marked them up 7½ inches, and that the house was built with these windows 7½ inches higher than the original plans called for. Now, the defendants say that was done in direct and distinct violation of their orders. The plaintiffs say that it was not; that their instructions were to make the windows high. It is argued to you that they would have no motive in departing from the instructions, and it is argued to you that they exercised their own good judgment and good sense in determining where it was best to place those windows. On the other hand, the defendants say that they were told explicitly to make them low. Now, gentlemen, that is wholly a question of fact for you, and you will determine whether or not the plaintiffs deliberately and wilfully increased the height of those windows in violation of the defendants' instructions.

The dining-room was to be oval in shape. A controversy has arisen as to whether it was so built. The plans and specifications do not show what kind of a ceiling the dining-room was to have. It is conceded by all parties that the room was to be broken upon the floor by a fireplace and chimney; they were to break the exact oval of the room. The plans show that. So far the intent of the parties is plain and easily to be understood. Now, the defendants say that they expressly told the

plaintiffs that the chimney-breasts should disappear at the lower point of the cornice in the room so as to give them an oval ceiling, and that they required it made so. They say that that was their express and explicit direction to the plaintiffs. On the other hand, the plaintiffs say that it was suggested to them, or that they suggested it to him. I do not think it is of any consequence from what source the suggestion came. The plaintiffs say that, having that in mind, and either from the defendants' suggestion that they would like to have an oval ceiling, or from their suggestion to him that it would make a very handsome room if it could feasibly be done, they made studies and sketches; that they went so far even as to make sketches that were finally submitted or shown to the builder, to the contractor, but the plaintiffs say that those plans were never adopted by the defendants; that they were only shown to them to see how far the idea could be worked out, hoping to do it if possible; that finding it impracticable, and feeling that the defendants would hold them responsible for having a chimney of a proper draught, and to avoid its smoking, they were unwilling to recommend it and to adopt it, and therefore they made the room as it is now made by carrying the chimney straight upward. Now, gentlemen, if the contention of the plaintiffs is the true one, and they and the defendants considered the feasibility of making this room in that way—if they talked about it and had conferences about it and made sketches of it, and finally it was left to the discretion of the architects to determine and they did determine to build it as they did—they were justified in doing so. If, on the other hand, as the defendants contend, they had specific instructions to build it the other way, and to have the chimney disappear below the lower edge of the cornice, it was the duty of the plaintiffs to build it so. It was the defendants' house. They were willing to pay the bills, and they had the right to have the dining-room, or any other room, built in any way they were willing to pay for, and it was the duty of the plaintiffs so to build it. But if, on the other hand, from the conferences and the talk between them, the plaintiffs were led to believe that they had no express or positive orders to so build it, but were only required to build it if it met with their approval, if it became feasible and would, in their opinion, give good results, why then, gentlemen, if they saw fit to exercise their own judgment, and did so in good faith, even though the defendants are displeased with it, it is no bar to the recovery of this case.

Now, gentlemen, the dormer windows and the dining-room come under the same consideration, in one aspect, that the paint and the French windows do, except that in the first two instances the defendants made the changes themselves and paid the bills. Now, in regard to these other two items, the dormer windows and the dining-room, I instruct you, as matter of law, that if the plaintiffs wilfully, disregarding the positive orders of the defendants, built the dormer windows high when they were directed to build them low, and built the dining-room with a broken oval in the ceiling when they were directed to give it a perfect oval, and if the violation of those orders has substantially injured the elegance, comfort, utility and value of the house, then the plaintiff cannot recover at all, because a man cannot be allowed to wilfully disregard the orders and directions of his employers, and then compel his employer to pay for the service. But, on the other hand, if any of these deviations were honestly and fairly made, and were not wilfully done in violation of the orders of the defendants, even though it did not come up to the contract or to the directions of the defendants, then, gentlemen, all that the plaintiffs would be required to do in such case would be to make the defendants whole, and the defendants, for any shortcoming of that sort on the part of the plaintiffs, would be entitled to have deducted from the bill the difference in value between the house they have got and the house they would have had if the architects had performed their duty according to their directions and requests. So you see that that question turns explicitly and directly upon whether there was any failure on the part of the plaintiffs to follow directions, and if there was, whether it was wilfully and purposely done in direct violation and disregard of the defendants' orders. In the one case, as touching these two last items, it bars their recovery altogether, and in the case of the first two items, the paint and the French windows, it allows them to be deducted from the bill, because the changes have been made and it is ascertained exactly what the damages would be. But if there was no wilful violation on the part of the plaintiffs, and they carried out the defendants' directions to the best of their knowledge, with discretion and skill, in the construction of this house, even though they may not have conformed to all the directions and requirements of the defendants, yet they would not be barred from recovery of their bill, but could only have deducted from their bill the amount which the defendants had pecuniarily suffered, and which would be the difference between the house as now built and the value of the house as it would have been had it been otherwise built, or built according to the requirements.

Now, gentlemen, there is one other consideration. It appears that in the contract there was included a stable, and

the plans and specifications were to cover the stable, and that some plans and specifications were furnished. It appears that a stable was built by the defendants, and the defendants contend that, inasmuch as certain framing plans or specifications concerning the stable were not furnished to them, which came within the duty of the plaintiffs to furnish, and for which they had paid, and which were refused to the defendants, that the plaintiffs cannot maintain this action. Gentlemen, that is not the law. They can maintain their action; but it was their duty to furnish the framing plans and specifications touching the stable; it was their duty to do it; they were paid for doing it. Now it does not appear that any of the work was delayed, or that a stable was not allowed to be built on account of the non-receipt of any of those things. It appears that the plaintiffs' bill concerning the stable was paid by the defendants. So, gentlemen, in that regard I instruct that the plaintiffs were bound, before they received their whole pay, to furnish all the necessary details and plans for the stable, and if they refused to furnish them, then, gentlemen, you must deduct from their bill such sum as you think, from the evidence, the plans so refused were reasonably worth. If, on the other hand, the defendants accepted the plans and did not call for the specifications, or waived them, and settled the bill, and made no claim on that account, and the settlement included all the controversy in regard to the stable, that is an end of the claim, and you will not concern yourselves about making any deduction for their failure to furnish specifications in regard to the stable. Otherwise you have the right to consider it, and to make such allowance as you think the plans that were so refused by the plaintiffs to have been reasonably worth.

Now, gentlemen, if you find a verdict for the plaintiffs you will add interest from the date of the writ. In regard to the rough-cast, that was left to the architects to decide, and their decision must be binding upon the defendants. It is not contended here that there was any such failure on the part of the plaintiffs in regard to the rough-cast as would change the result of this case.

There are one or two things that have been suggested to me that I may have omitted, and that is in regard to the dormer windows and the dining-room. I supposed I had stated to you (I will do so now at any rate) that if they were built by the architects in the exercise of their own good judgment and discretion, and not in the wilful violation of orders, why then the defendants have no claim on that account if they were built as ordered.

Then it is suggested to me that I told you that a plan was submitted to Mr. Hodgkins for consideration by him. I do not know that I said so, but if I did so state you have heard the evidence as to what the plan was submitted to him for. I did not mean to preclude you in any way about that, and I do not know as it is material. I did not intend to say to you that the plan was submitted to him to determine anything, because I do not know that it was.

I am requested by the learned counsel for the defendants to instruct you that—

"If you find that the house was not built in accordance with the defendants' instructions to the plaintiffs, and such departure was the result either of the negligence or wilfulness of the plaintiffs, then there shall be deducted from the amount that would otherwise be due to the plaintiffs whatever damage the defendants have suffered on account of the departure."

Yes, gentlemen, I give you that instruction.

The jury gave a verdict for the architects, on all points.

WILTON HOUSE.

THE members of the Newbury District Field Club visited Wilton on the first excursion of the season. After seeing the Carpet Factory, Almshouses, Fugglestone Church, Wilton House, the home of the Herberts, was reached. The mansion, which stands in a fine park, says the *Reading Mercury*, consists of an extensive pile of buildings erected at different periods and in various styles of architecture. It has engaged the attention of several eminent architects, the original designer being Hans Holbein. When his pile was injured by fire the restorer was Inigo Jones, and his son Webb, who were employed in enlarging or embellishing it, and later on Wyatt was engaged, and designed an enclosed or glazed cloister for the reception of the valuable works of art which the owner had collected; also a large courtyard on the north and a new side to the house. In the opinion of Sir Richard Hoare the work of Mr. Wyatt was not attended with the most satisfactory results; in short, the building cannot be said to belong to either of the great men mentioned. A specimen of Holbein's architecture, however, still exists, a porch and gateway of strikingly beautiful proportions, containing two series or stages of pillars, one above the other, as well as recesses with busts. Architecturally Wilton House is not to be compared to Castle Howard or some of the other great mansions which make our English noblemen appear like so many lesser sovereigns on their own domains, but in its associations

Wilton surpasses nearly all of them. The grand entrance hall, for instance, and cloisters, the latter extending round the four sides of the noble pile, contain several hundred pieces of ancient sculpture of incalculable value, and suits of armour of fabulous worth. The pictures in this splendid collection are not less valuable than the sculptures, consisting as they do chiefly of the works of Reubens, Vandyke, Spagnoletto and Parmegiano, a portrait of Titian (by himself) and a large family piece in the drawing-room, by Vandyke, of Philip, Earl of Pembroke, with his countess, Susan, daughter of the Earl of Oxford, and their five sons and daughter Anna Sophia, and her husband, the first Earl of Carnarvon. This nobleman, who is represented as attired in cavalier costume, fell in the battle of Newbury. As many of our readers are aware, the Pembroke family is related to that of Carnarvon, and we were informed that had the late Earl of Pembroke died without male issue, the late Earl of Carnarvon would have succeeded to the estates. Genealogists deduce the origin of the Herbert family from a natural son of Henry I., whose descendant William, son of Sir William ap Thomas, was created first Earl of Pembroke, and being warmly devoted to the Yorkist party, was beheaded by the Lancastrians after the battle of Edgecote, where he had been taken prisoner. His son William, the second earl, had for his third wife Mary, sister to Sir Philip Sydney, on whom Ben Johnson wrote a beautiful epitaph. The third Earl William, called by pre-eminence the Earl of Pembroke, was a truly illustrious character. The visitors having been received in the hall, were successively conducted through the cloisters, the Gothic hall, where, through a break in the wooded scenery of the park, a delightful glimpse of the graceful spire of Salisbury Cathedral was seen; the colonnade-room, the breakfast-room, containing a fine portrait by Richmond of the present holder of the title, George Robert Charles, the thirteenth earl; the library, from which there was a fine view of the terraces and Italian garden, with the lovely walk, terminating with the Italian summer-house, containing a replica of Shakespeare's statue at Stratford-on-Avon; the dining-room and other apartments, all more or less magnificently adorned with painted ceilings and elaborate cornices. The visitors were conducted through the reception-rooms in small parties by the housemaids who were in charge of the mansion, the earl and countess being at their town house, and it was a matter of disappointment and regret that no one was in attendance capable of imparting some reliable information in reference to the multitude of fine art treasures which met the eye at every turn. The visitors were literally hurried through the mansion, where much more time might have been spent to the advantage and pleasure of all. On their departure they were met by Mr. Challis, the head-gardener, who has been in the service of the family for thirty-five years, and who conducted the party through the delightful grounds, pointing out various objects of interest, including trees planted by the late Emperor of Russia prior to the Crimean War, and by other distinguished personages. The park contains a fine herd of deer, and it is timbered with a great variety of valuable trees, including elms equalling those in the precincts of Eton College, brown beeches, noble oaks, wide-spreading cedars, grown from saplings brought direct from Lebanon, and the evergreen oak, known as ilex, the latter probably three hundred years old. It has suffered much damage from frost and tempest, and its branches are now held up by timber supports. Through the park run two streams, the Nadder and the Wiley, both of which fall into the Avon near the adjacent cathedral city. Spanning the Nadder in its winding through the park is an elegant Palladian bridge of Classic appearance, from which were espied some splendid trout. The tour of the grounds was made in the face of drenching rain; still, with such an intelligent and communicative guide as Mr. Challis, there was no lack of interest. Mr. Challis explained that when, in compliance with the wish of the present countess, some excavations were being made close to the river front of the mansion with the object of planting some climbers, two tombs of great antiquity and interest were unearthed, and they are now preserved in one of the Italian summer-houses in the park. Crosses are carved on each. One tomb is of the eleventh century and one of the thirteenth century. They probably marked the site of the burial-place connected with a nunnery which stood on the spot now occupied by Lord Pembroke's house, founded far back in Saxon times. A ruin of the original buildings and a window of great antiquity were pointed out. On the dissolution of the monasteries, the lands were conferred by Henry VIII. upon Sir Wm. Herbert, afterwards Earl of Pembroke.

The town hall was afterwards visited. The ancient charters, the gold maces, and other civic insignia were exhibited and inspected with much interest. We were informed by the Mayor that Wilton is one of the oldest corporate boroughs in the country, and is only surpassed in its antiquity by Winchester, London and York. Its first charter was granted in the year 1100, prior to the laying of the foundation-stone of the magnificent cathedral at New Sarum, which took place in 1220.

The town is situate in a fertile vale at the confluence of the Nadder and the Wiley, three and a half miles from Salisbury, and is called by some old writers Vilodunum and Ellandunum, and by Baxter Caer Guilon, or the chief seat of the British Prince Carvilius. However this may be, it is undoubtedly a place of great antiquity from which the county derives its name, and it was probably a chief town and residence of the West Saxon kings, who conferred upon it many substantial marks of their favour, such as founding religious establishments, constituting it a royal borough, and investing it with many extraordinary immunities. King Alfred defeated the Danes here in 871. The place was particularly famous for its abbey, which was instituted in 773 by Wulstan, Earl of Wiltshire, on the occasion of his having defeated the Mercians, who had put to death his father Alquimond. About the year 800 it was converted by Egbert into a nunnery, and in 871 Alfred transferred the religious, whose number he augmented, to a new establishment.

OSCOT COLLEGE.

ON Saturday forty-five members of the Midland Institute and their friends drove in open carriages to Oscot College. They were there met by the Rev. Dr. H. Parkinson, the Rev. Canon Greaney, and the professors and gentlemen resident at the college. The party were divided into six groups, and placed under the care of as many gentlemen, who led them by different routes through the principal apartments. The buildings were erected, says the *Birmingham Post*, by the elder Pugin about the year 1836. They are in the style which prevailed in collegiate and domestic buildings towards the end of the fifteenth century, and are arranged round a large central quadrangle; the details are extremely simple throughout, but the large and lofty structure, relieved by a massive tower, has great dignity of effect, and, standing as it does on an elevated and exposed site, forms a predominating feature in the landscape from several directions. The chapel is a conspicuous feature, and, though perhaps somewhat lacking in dignity, is very pleasing and attractive. The magnificent reredos is decorated with paintings and Limoges enamels, and the effective colour decorations of the walls and arches compensate for the rather bare character of the architecture. There are several chapels. The apartments which formed the chief attractions were the library and museum. Only those of the party who had previously been through these departments could have had any idea of the extent and value of the collections. Many of the illuminated manuscripts were each worth a much longer journey than to Oscot. One small volume of the thirteenth century of remarkable caligraphy and exquisite miniature painting, all in wonderfully good preservation, had whole page drawings of apostles and saints of great excellence of drawing and of colour, the latter remaining nearly as bright as it was six hundred years ago. The manuscripts are a fine series extending from the thirteenth to the sixteenth centuries and form a valuable means of studying the gradual changes of style, and the series is continued in early printed and illustrated books, the binding alone being in many instances of rare beauty and excellence. The embroidered vestments, from the thirteenth to the seventeenth centuries, are exceedingly fine; many of them belong to St. Chad's Cathedral, but it was quite impossible during the time allotted to see a twentieth of the treasures of the library. The same may as truly be said of the museum, to which the party were next conducted. The nucleus of the museum was formed by Pugin, and consisted to a great extent of small carved Mediaeval statuettes of wood, many in good preservation and containing much of the original painting. There are also figures in stone and alabaster, many very exquisitely carved, painted and gilded triptychs, and other work in wood and metal. An exceedingly fine bronze eagle desk, with statuettes, pinnacles and other architectural adornments, is perhaps the chief object of the collection. This was presented to St. Chad's Cathedral by Henry, Earl Shrewsbury. It is probably the finest thing of its kind in the world. A small wrought-iron receptacle for burning a charcoal fire is made to represent a fortress, with towers, bastions, drawbridges, gates, &c., an extremely curious and interesting work. A crucifix, carved out of a very large single piece of ivory, is one of the great treasures of the college, and originally belonged to the Emperor Napoleon. Much of the church plate is very fine and valuable. Before leaving the visitors partook of light refreshments, and a vote of thanks was proposed by Mr. J. A. Cossins to the Bishop of Birmingham, Canon Greaney and Dr. Parkinson for the privilege of visiting the college, and to the gentlemen who had proved such intelligent and courteous guides.

Colonel Charlesworth, M.P., has given 250*l.* towards the restoration of Grinton Church in Swaledale. The renovation will cost some 2,000*l.*, and already nearly 1,000*l.* has been raised.

GENERAL.

The French Government have subscribed 1,000*l.* towards the cost of finishing Turner's *Ancient Italy* for the Louvre.

The Plans by Messrs. Cooper & Howell, of Reading, have been adopted by the Reading Town Council for the extension of the Free Library and Museum Building. The plans by Mr. W. G. Lawton obtained the second prize.

Herr Palmie, the Munich painter, has patented a packing-case, which he claims will afford security against injury for all paintings enclosed in it. A company will be formed for the manufacture of the cases.

Mr. Robert Walker, of Windermere, has obtained the first prize in the competition for a Board school in Lancaster.

Sir Henry Oakley, general manager of the Great Northern Railway, is shortly to be presented with a life-size portrait of himself as a memento of over forty years' connection with the company. The cost of the work has been subscribed by the officials of the company in every grade of the service.

The Bradford Society of Architects and Surveyors contemplate making a two days' trip over the Manchester Canal in the month of July.

Major Seymour Leslie, R.E., read a paper on "The Threatened Temples of Philæ" at the meeting of the Society of Architects on Tuesday, a report of which will appear next week.

The Annual Excursion of the Architectural and Archaeological Society of the counties of Lincoln and Nottingham has just been held in the neighbourhood of Horncastle, a number of interesting Lincolnshire churches being visited.

The Glasgow Archaeological Society have passed a resolution deprecating the removal of the Tron Steeple, which, erected about 1637, has been for over 250 years one of the best-known and most picturesque landmarks of the city.

Mr. H. M. Townsend, architect, has written a letter to the *Standard* alluding to the dangerous condition of Fotheringay Church. "The present incumbent," he says, "feels the greatest interest in the church, which, besides its historical value, is full of architectural beauty, and I hope that the attention now called to the matter may result in his receiving some assistance towards preserving the remains of a noble church with a deeply interesting history."

The Olympic, which has never been a success as a music-hall is to be re-offered for sale. The original building was known as the Olympic Pavilion, but this being burned down in 1849 the present structure was erected. The auditorium is said to accommodate 3,000 persons, and the stage is in size second only to that of Drury Lane. The whole covers an area of 14,000 feet superficial, with frontages to Wych Street and Maypole Alley.

A British Committee, of which Sir Douglas Galton, K.C.B., F.R.S., is the chairman, and Professor W. H. Corfield, M.A., M.D. (Oxon), is the treasurer, has been formed to further the interests in this country of the eighth International Congress of Hygiene and Demography, which is to be held in Budapest from September 1 to 8 this year.

The Death is announced of M. Federico Madrazo, the Spanish painter, at the age of seventy-nine. At his death he held the high position of Director of the Academy of the Fine Arts, and of the Museum of Painting in Madrid.

The Tower Bridge was inspected yesterday by the members of the City of London Corporation.

A Sum of 3,000*l.* has been received in aid of the building fund for the new church of St. Aidan, for Walton and Bamber Bridge.

The Sale of the seventeen paintings belonging to M. Tavernier, which were on view last week at the Petit Gallery, in Paris, brought a total of 12,160*l.* The one that sold best was M. Eugène Delacroix's *Entombment*. It was knocked down at 3,520*l.* The *Laundresses Washing in a River* of Daubigny fetched 2,720*l.*; *Arab Horsemen Crossing a Ford*, 840*l.* (Delacroix).

Wetton Village Church was reopened yesterday (Thursday). Messrs. Wm. Sugden & Son, of Leek, were the architects, and Mr. J. W. Bassett, of Hulme End, the builder.

"Gog - Magog Hills," the celebrated Cambridgeshire estate of the Duke of Leeds, is in the market. It comprises a fine mansion within the famous Roman entrenchment known as Vandlebury, 250 feet above the level of the sea, and close on 500 acres.

The Site of Her Majesty's Theatre in the Haymarket, which was intended to be utilised for an American hotel, is to be brought to the hammer early next month. It is stated that an attempt will be made to secure it for the erection of a grand national opera house.

The Transactions of the British Association for 1893, embodying the report of the Nottingham meeting, have been published in a volume of over 1,000 pages. The publisher is Mr. John Murray.

The Architect.

THE WEEK.

AS MR. WILLIAM CALDER MARSHALL was one of the "Honorary Retired Academicians," his name had become unfamiliar to modern amateurs. At one time he was the strongest of FOLEY's rivals, and from his studio in Ebury Street, which he occupied for over half a century, a great many works were turned out. His *Sabrina*, which was made popular by a porcelain copy, was a graceful figure, and by many it is considered his representative work. His statues of CLARENDON and SOMERS in the corridors of the Houses of Parliament displayed ability to model figures of men, and his *Agriculture*, which forms part of the Albert Memorial in Hyde Park, is also effective. The statues of PEEL in Manchester, of CROMPTON in Derby, of JENNER in Kensington Gardens, are among his works. In the competition for the Wellington Monument he obtained the highest premium of 700*l.*, but he was not entrusted with the commission. The panels which he executed in the chapel where STEVENS's monument used to stand were not compensation for the loss of the greater work. MR. MARSHALL was born in Edinburgh in 1813, and there he received his earliest instruction. When he came to London he was employed by CHANTREY and E. H. BAILEY. The influence of both Academicians is visible in his figures. In 1844 he was admitted an Associate of the Royal Academy, and in 1852 he was elected Academician. Sculpture can only attract limited patronage in England, and it was creditable to the late W. C. MARSHALL that he was persistent in producing conscientious work alone.

THE artists who have possession of the surviving buildings of the last international exhibition in the Champ de Mars are likely to suffer inconvenience before long. It was intended at one time that their galleries should not be affected by the laying-out of the ground for the buildings of the international exhibition which is to be held in 1900. But that arrangement has had to be altered. A meeting of the sub-commission charged with the preliminary operations was held on Monday, when it was decided that the Eiffel Tower is alone to have a guarantee of preservation on the Champ de Mars, and the Trocadéro buildings are to be also respected on the opposite of the river. With the two exceptions the competitors for laying out the grounds and designing the buildings are to have the fullest liberty in dealing with the site. It is probable, however, that many of the competitors will believe in the prudence of allowing the existing galleries of fine arts to remain. Prizes amounting to 4,000*l.* are to be awarded for the designs.

M. ALFRED HENRI BRAMTOT, who died a few days ago at Garennes in his forty-first year, was one of those painters who are indifferent to the applause of the crowd. His *Departure of Tobias*, which was reproduced in *The Architect*, exemplified his aims. He wished to represent biblical scenes of the same class in a manner that did justice to their idyllic character, and was yet most reverential. His treatment was the more remarkable, as M. BRAMTOT won the Prix de Rome in 1879. He was a native of Paris, and studied under M. BOUGUEREAU. In order to secure independence of the market, and do justice to his talent, M. BRAMTOT occupied a great part of his time in teaching. He was one of the professors in the Académie Julian and in the Ecole Polytechnique.

ANOTHER of the veterans of English architecture has passed away. MR. JAMES MEDLAND died at Gloucester on the 18th inst., at the age of eighty-six. The son of an architect in practice in London, he came to Gloucester as chief architectural assistant to the late MR. S. W. DAUKES, remaining in that position when the practice was continued by DAUKES & HAMILTON. When MR. DAUKES left Gloucester for London, the firm became HAMILTON & MEDLAND. MR. HAMILTON subsequently left MR. MEDLAND in sole possession. After some years he was joined by MR. MABERLY, and, on MR. MABERLY's retirement, by his son. MR. MEDLAND held for many years the office of county

surveyor. Since the office was first opened in Clarence Street by MR. DAUKES a great many buildings, some of them large and important, have been carried out. In the list are comprised lunatic asylums, workhouses, cemeteries, public halls, hotels, markets, churches, chapels, police-stations and petty sessional courts, mansions and smaller dwellings, workmen's cottages and sundry other buildings. In the designs of all of them MR. MEDLAND took the chief part. His eldest surviving son, HENRY, is still in practice in Gloucester. A younger son, JOHN, is a member of the firm of MEDLAND & POWELL, and was for several years one of the late Sir G. G. SCOTT's managing assistants and chief draughtsmen.

THE advantages of Bexley Heath, in Kent, for suburban residences, on account of its healthiness, picturesqueness and accessibility from London, are strangely overlooked. If it had been remote from the metropolis, instead of being twelve miles distant, its scenic beauty would have found countless admirers. It is to be hoped the small book entitled "Bexley Heath considered with regard to Health," by DR. O. SUNDERLAND, the medical officer of health (published by T. JENKINS), will receive the attention which the subject deserves. Many of the suburban districts are overcrowded, and it is a public benefit to possess one which for nearly a century has possessed a reputation as a health resort, and which, as DR. SUNDERLAND explains, is not due to accidental causes. The ground consists of beds of sand and gravel resting on chalk, averaging 130 feet in depth, and fogs are almost unknown. The rainfall is diminished mainly by the influence of Shooter's Hill, and there is protection against northerly and easterly winds. According to DR. SUNDERLAND, "Bexley Heath possesses a climate suitable for all persons who require a bracing atmosphere and a dry soil." That the district has a curative effect on many diseases has been repeatedly demonstrated. The illustrations are evidence that what is said about the picturesque charms of that part of Kent is not exaggerated.

THE grouping of the contents of an international exhibition is no easy task, and various systems have been adopted since 1851. In the Paris exhibition of 1900 there will be seventeen groups, which will be subdivided into 117 classes. The first will relate to education and teaching. The second will comprise works of art, including painting in oils and water-colours, engraving, lithography, sculpture, engraved stones, and lastly architecture, which will be again recognised as one of the fine arts. The third group will exemplify instruments and processes employed in literature, science and art, including photography, musical instruments, printing, theatrical properties, &c. Machinery in general will form the fourth group. The fifth will be devoted to electricity, which by the end of the century is certain to have reached a remarkable development. The sixth group will display examples and models of civil engineering and means of transport. Four groups will be required for agriculture. Mines and metallurgy will constitute the eleventh group. The twelfth will be an attractive one in France, as it will relate to the decoration of buildings and furniture. One of the classes will be formed of painted glass, which hitherto has had an uncertain position, being sometimes treated as a manufacture. The thirteenth group will comprise textiles and clothes. Chemical products will constitute the fourteenth group. The fifteenth and sixteenth groups will suggest the weakness of all classification, for one will contain industries, such as goldsmiths' work, cutlery, watches, which might be supposed to belong to some of the earlier groups, and the other will suggest sanitation. Finally will come arms—for without their aid there would be little safety for the works of peace which it is the object of an exhibition to exemplify.

AN illustrated volume entitled "Three Periods of English Architecture," by MR. THOMAS HARRIS, F.R.I.B.A., will shortly be issued by MR. BATSFORD. In the pages the author explains the growth of opinion amongst his professional brethren upon the necessity for some considerable advancement of their art in accordance with the necessities and spirit of the present day. He also dwells upon the advantages offered in our time for a new departure, such as many able architects have already indicated.

A HISTORY OF WESTMORLAND.*

FROM its physical conformation the Westmoringa land of the Saxons, which has been known at later periods as Westmaria, Westmeria, Westmerieland, Westmerland, the land of the western meres or lakes, Westmoreland and Westmorland cannot be remarkable for fertility, but it never lacked inhabitants. Probably the security it offered was considered to be an equivalent for the distances which separated the valleys that are covered with soil. In our time the picturesqueness of the greater part of the county has made Westmorland attractive for residential purposes, and the inhabitants can obtain supplies from distant regions. The agricultural fertility, therefore, does not count for much. For many centuries the people were compelled to rely on what was obtainable from the valleys and the hill-sides, which in primitive days must have been uncertain in quantity, yet there is evidence enough that many a contest was fought to secure the privilege of living among the northern mountains and near the lakes.

Ethnographic research has furnished evidence of a diversity of possessors, and reveals that in all times inhabitants had to make way for strangers who were stronger, better armed, more influential or wealthier. There was a long-headed race using stone implements who were supplanted by round-headed men who could fashion stone into more efficient weapons, and then came invaders who were armed with bronze javelins who would be irresistible—for a time at least. Memorials of these remote possessors remain, and the student of prehistoric archaeology will have enough subjects for investigation in Westmorland. Mr. FERGUSON in the course of his chapter on the early inhabitants says:—

The round barrows and cairns of the brachycephalic men are numerous in Westmorland, and are found on almost every fell. Several in the parishes of Kirkby Stephen, of Warcop, of Asby, of Crosby Garrett, of Ravenstonedale, of Orton, of Crosby Ravensworth and of Askham have been excavated by Canon Greenwell, who has put on record the results. Cairns abound upon Moor Divock, the high plateau between the foot of Ullswater on the west and Helton Flecket on the east. The late Dr. M. W. Taylor, F.S.A., of Penrith, was the first to call attention to the existence among these of "starfish cairns," or cairns with projecting rays like the arms of a starfish. The conjecture is that the projecting rays cover secondary interments. Megalithic monuments, such as upright stones, or *menhirs*, stone circles and stone avenues, are common; such as the Kop stone on Moor Divock and the Guggleby stone at Shap, the stone circles and avenues at that place and on Moor Divock, the stone circles on Lowther Scar, at Crosby Ravensworth, at Leaset Wood by Clifton Dykes, at Gamelands, and elsewhere. Under the name of Carl-Lofts the megalithic remains at Shap have attained a reputation they are hardly entitled to. The country people tell legends of an avenue of *menhirs* extending from Shap to Moor Divock, a distance of at least seven miles. Pennant and Stukeley more modestly mention an avenue of one and a half miles, extending from the village of Shap into the precincts of Shap Abbey, and some modern antiquaries have laboriously amused themselves by endeavouring to reconstruct the "serpentine avenue" of Stukeley. But the Rev. W. C. Lukis, F.S.A., who surveyed in 1884 the megalithic remains at Shap on behalf of the Society of Antiquaries of London, thinks that this avenue had no existence on such a scale. Pennant's account is based, he shows, upon that of Stukeley, who visited Shap on a rainy day in 1725, in weather, therefore, by no means favourable to archaeological research on a bleak and exposed moor. From Carlisle Stukeley sent over to Shap a young and inexperienced surveyor named Routh, who in one day (an utter impossibility) made a plan of the Shap megalithic remains, which cannot now be found among the Stukeley papers. Mr. Lukis, who edited the Stukeley papers for the Surtees Society, concludes that the serpentine avenue from Shap to Shap Abbey is due to the vivid imagination of that ancient antiquary. Further, Mr. Lukis, after a careful survey of the existing remains and due consideration of the evidence as to what has disappeared, is of opinion that Shap was a necropolis extending over a considerable area, and that there may have been single and double rows of stones, but not necessarily as part of a specified system. Moor Divock would seem to be also a necropolis on a large scale, and the same might be said of the vicinity of Crosby Ravensworth. Several stone circles, known on undoubted evidence to have existed in various parts of the country, have disappeared under the ravages of the builder, the agriculturist or the roadmaker.

The early inhabitants also found it was necessary to protect the living as well as to preserve the memory of the dead. Round or oval camps and enclosures are met with which date from Neolithic days. On Moor Divock there is a circular space 68 feet in diameter, which is entirely paved with water-rolled stones. Similar pavements have been found in Algeria. It is supposed that at least three

aces, a pre-Celtic and two Celtic, had occupied Westmorland prior to the coming of the Romans, but where they came from and how long they remained have yet to be ascertained. The Brigantes who are referred to by PTOLEMY are supposed to have inhabited Westmorland, besides Cumberland, Northumberland, Yorkshire and Lancashire, but whether they formed a tribe or combination of tribes can only be guessed. Apparently in CÆSAR'S time the people in the north were less civilised than those in the south.

The northern tribes were on that account not easily converted to a belief in the advantages of the improved systems of government and life introduced by the Romans. It was necessary to erect earthworks and fortifications to protect the strangers and the Britons under their rule. Westmorland could not be omitted or neglected by the Roman engineers, but it does not appear as if that district possessed much importance on its own account. As Mr. FERGUSON says, the Roman stations in Westmorland were few, and if compared with those in Cumberland were unimportant, for "they covered no frontier, like the stations on the line of Hadrian's Barrier, they protected no harbours, like those that studded the Cumbrian coast of the Solway. Their duty was to guard the lines of communication between these frontier posts and ports and the military basis of operations, whether that basis was at Chester as in the early days of the Roman dominion, or at York, as in the latter days."

A long period followed the Roman occupation, which is not represented by constructive works in Westmorland. There is a tradition about UTHUR PENDRAGON, the father of King ARTHUR, having a house at Mallerstang, "where heavy earthworks denote something earlier than the small Norman keep now in ruins," but only a poet could attach importance to either the tradition or the remains. There were many fierce struggles in and around Westmorland, which Mr. FERGUSON does his best to explain. For nearly five centuries it was alternately Saxon and British or Welsh, according to whatever power was temporarily uppermost. The condition of that part of the country at the time when the Domesday Survey was prepared is suggested by an entry relating to about fifty villages in the hundred of Amounderness, which says, "Of these, sixteen have few inhabitants, but how many inhabitants there may be is not known; the rest is waste." WILLIAM RUFUS in 1092 took possession of Westmorland with the rest of the land of Carlisle, and he displayed more wisdom than might be expected from him, in imitating the Romans by raising constructive works to guarantee security.

The first care of the English king was to make his dominions safe against invasion from Scotland, and to secure the great road from York to the north over the pass of Stainmore. This he did in the most approved fashion of the day. The military engineers who served his father had introduced from Normandy the fashion of building castles in stone, with, where the ground was firm enough to carry the weight, great square keeps within their enceinte; the Tower of London is the finest example thereof in England. For the erection of such keeps the waste chert or camps of the Romans offered facilities of a high order—their strategic positions, selected by men who thoroughly understood the art of war; the rich quarries their abundant ruins presented of hewn and wrought stone all ready to hand, and the firmness of the ground, consolidated by long lapse of time, on which they stood. The "burhs," or great earthworks, with which the thanes or franklins, who preceded the Norman barons, had studded the land, were also well fitted for that purpose. For the defence of the great road from York over Stainmore William Rufus reared square Norman keeps on the Roman camps of Bowes in Yorkshire, of Brough-under-Stainmore and of Brougham in Westmorland, and of Carlisle on the sites of Roman *Lavatrae*, *Verterae*, *Brovonacae* and *Luguvalium*. Another of these square keeps he placed on the site of the "burh" of thethane or franklin of Appleby, and yet another on the "burh" of Pendragon, to guard the by-pass of Mallerstang. This chain of castles guarded the only road open for wheels from Carlisle and the West of Scotland into the heart of England, the great plain of York. A castle at Bewcastle stopped the Maiden Way on which, owing to the gradients, wheels could not be used. For the time this seems to have been thought sufficient; no Norman castle was built on the "burh" of thethane or franklin of Kendal; the Red King's advisers do not appear to have been apprehensive of an invader from either Scotland or Ireland landing on the Cumbrian coast and working south by the Roman roads to Windermere and Kendal; they seem also to have thought the impervious and roadless defiles of Shap required no fortifications. These castles were built by, or under the superintendence of, Flemish masons, of whom the Red King imported a considerable number, who probably remained in the country as settlers.

The Norman keeps were not only useful for the defence of a great road. Afterwards they became the models for

* *Popular County Histories: A History of Westmorland*. By Richard S. Ferguson, M.A., LL.M., F.S.A. London: Elliot Stock.

the much smaller peel towers, which were indispensable as residences during border warfare. The towers were so numerous that, as Mr. FERGUSON says, "It is a common remark at every archæological meeting in the county that the kernel of almost every 'hall house,' and of many an old farmhouse, in Westmorland as in Cumberland, is the lower storey of a peel tower, round which the rest of the building has gathered. . . . In some cases the peel tower makes no sign that the eye can see, and the curious archæologist has to search for its remains, probably the lower storey only, in the strong-room, the plate-closet, the ale-cellar or the dairy, where its existence is at once betrayed by the great thickness of the walls compared with more modern additions." Up to the fourteenth century the tower was sufficient for residence, then a hall was added as a distinct building; afterwards there was further extension, for during the sixteenth century mansions began to assume the form of ranges of buildings facing a courtyard. In some cases, whilst the old peel tower and dining-hall were retained, another tower in symmetry with the original one was added to the opposite end of the block, so as to give the form of the letter H. Owing to the fashion for absorbing smaller estates which prevailed among the LOWTHERS and other great families, "many manorial halls have come to the condition of mere farmhouses."

In Westmorland and Cumberland defensive requirements made it necessary to have courageous and trustworthy men in most districts. Hence it was probably that the "statesmen," *i.e.* estatesmen, or peasant proprietors, arose. They still form a remarkable class of men. People in the south were first made acquainted with their qualities by the writings of WORDSWORTH, SOUTHEY and JOHN WILSON. A bold peasantry like them may be their country's pride, but they can never be patrons of architecture. The dwellings have been considered as picturesque, especially when creeping plants cover the walls and flowers are in bloom in the gardens, but constructively they are very simple:—

The cottages of the dalesmen or "statesmen" were built of unhewn stone, sometimes without mortar, and roofed with rough slates; the woodwork throughout was of oak; the beams were made of whole trees roughly squared with the axe, while the smaller rafters and joists were split. The houses of the usual size contained, as a rule, only three rooms on the ground floor, viz. the kitchen or general sitting-room, the dairy and the parlour, where the master and mistress generally slept; stone steps gave access to the loft, an unceiled apartment, generally divided into two and used for sleeping; an outhouse or downhouse with set-pot, and a huge porch, completed the accommodation.

The dwellings of a people have a close connection with the history of the district containing them, and in those of Westmorland it is easy to perceive evidence of one of the qualities of the inhabitants, which was an indifference to external influences. The remoteness of Westmorland and the neighbouring region is indicated by the uncertainty of its ecclesiastical relations. At one time the bishops of Glasgow and Durham claimed to be the overseers of the souls of the inhabitants, at another time the barony of Appleby was part of the diocese of Carlisle, while the barony of Kendal formed part of York. HENRY VIII. placed the latter in the diocese of Chester. The people do not appear to have cared much about hierarchical arrangements, which was not surprising, for a large part of them were of Scandinavian race. Mr. FERGUSON has to admit (and it cannot be satisfactory to a diocesan chancellor) that "Westmorland is not very rich in religious houses: a house of Carmelites or White Friars at Appleby; a cell at Bleatarn, near Warcop, which was a dependency of the Cistercian abbey of Byland, in Yorkshire; and an abbey of Premonstratensians, or White Canons, at Shap or Heppe, as it was originally called, complete the list." There were enough churches in the old days, but the scarcity of abbeys was the sign of the absence of an element of organisation which was most powerful in the remainder of England.

If ecclesiastical authority was weak in Westmorland, one of the consequences was abnormal selfishness, which was seen in some of the great families. Mr. FERGUSON, after narrating the history of the CLIFFORDS, tells us they were "a race of singular energy, which found vent for itself in fighting, in adventure, in building, in litigation, in extravagance and gallantry, and frequently in rebellion against their sovereign," all of which actions caused sufferings to other men with which a historian is not expected to sympathise.

It is satisfactory to learn that there was a change of manners accomplished by bringing up the head of the house from a boy as a shepherd. In him, as WORDSWORTH says, "the savage virtues of his race, revenge and all ferocious thoughts were dead." As became a good man, the shepherd-lord "occupied himself in repairing and rebuilding his numerous castles." The hereditary impatience of the ordinary English life afterwards reasserted itself in some of his descendants. Among them was the famous Countess of PEMBROKE, who "spent in building operations 40,000*l.*, and when told that CROMWELL would pull her restored castles down, she declared that she would rebuild them as fast as he should destroy them." She was "High Sherifess" of the county, and was competent to fill a higher office. It was the Countess who was supposed to have written the famous curt reply to a Secretary of State after the Restoration when a Government candidate was proposed for Appleby:—"I have been bullied by a usurper, neglected by a court, but I will not be dictated to by a subject. Your man shan't stand."

With lords and ladies above them like the CLIFFORDS, it is no wonder the people were tenacious of the rights which they claimed to have held from the time of King BRUTE, and on any sign of interference were ready to cry out that the landlords intended "to pull their skin over their ears and bray their bones in a mortar," or to commit similar misdeeds. Combativeness was developed, and the wrestling and other athletic sports may be considered as forming a weak survival of the old spirit which was displayed in many moving accidents by flood and field.

It is one of the advantages of the series of county histories published by Mr. ELLIOT STOCK that each writer is allowed to realise his own theory of the character which should be given to his work. Mr. FERGUSON is a lawyer as well as an archæologist, and he is moreover enthusiastic about every trace of antiquity which can be revealed in Cumberland or Westmorland. His book is therefore well balanced. It is plainly the work of a man who finds pleasure in his investigations, but who submits to the restraints which laws of evidence impose. The statements in the pages may be accepted with confidence, and they are so disposed as to form graphic pictures of life in the north during several centuries.

A VISIT TO CLUNY.

IN the *Glasgow Herald*, Mr. Dalrymple Duncan, one of the secretaries of the Glasgow Architectural Society, gives the following account of a visit to the abbey of Cluny, one of the homes of architectural art:—

In travelling through France it is melancholy to see the condition into which a great many of the important architectural monuments of the country have been allowed to fall, and in most cases if the tourist asks an explanation he will be told with a shrug that the destruction took place in "Quatre-vingt-treize," for, like our own Reformation, the French Revolution is a convenient scapegoat on which to lay the blame of a state of matters due in numerous instances both in Britain and France to the neglect or the vandalism of municipalities or individual proprietors. The Reformation and Revolution have their own share of blame to bear, but it is unfair to charge them with acts of destruction for which they are in no way responsible. In France it is deplorable to think that the great abbey church of Clairvaux, after having passed unscathed through the troubles of the Revolution, the Directory, the Consulate and the First Empire, should have been wantonly swept away and the tomb of St. Bernard destroyed as late as 1816, when the Bourbons had been restored to the throne of their ancestors. The splendid church of St. Bertin in St. Omer, one of the chief architectural monuments of the north of France, was demolished in 1830 (with the exception of the tower and a few inconsiderable fragments) by the municipality, under the pretence of giving employment to the people. The fine cathedral of Arras (which dated from the twelfth century) was destroyed during the reigns of Napoleon I. and Louis XVIII. Nor has so-called "restoration" been a less important factor in the destruction of many of the most interesting buildings of France. The abbey church of St. Front (now the cathedral) in Périgueux, which dated from the tenth century, and was one of the most important examples of the Byzantine style in Europe, has been virtually rebuilt and deprived of all character. The curious church of St. Germigny-des-Prés, in the Orlennais, built at the beginning of the ninth century on the model of the cathedral of Aix-la-Chapelle, has

been similarly treated. The old abbey church of Brantôme has been so scraped and tinkered at that it might pass for a newly-erected *quoad sacra* in a Scots manufacturing town. But among all the instances of nineteenth-century vandalism which can be quoted, none of them surpasses the deplorable destruction of the great abbey church of Cluny, which, after St. Peter's at Rome, was the largest church in the world, and could hold 30,000 people.

A visit to Cluny can easily be managed from Mâcon, from which it is only 15 miles distant and the trouble of the journey will be well repaid. Apart from the remains of the great abbey the little town contains two churches of very considerable importance, and in its narrow streets possesses more examples of the domestic architecture of the twelfth, thirteenth and fourteenth centuries than any other place in France. But it is chiefly as the cradle of the great Order which there sprang into being that there will always linger around the valley of the Grosne a special and peculiar interest. In the heyday of the Order, 314 monasteries scattered over the length and breadth of Europe owned the sway of the abbot of Cluny, who was really the head of a little principality, coining his own money and directing the affairs of the brotherhood without even admitting the dictation of the Pope himself.

It is curious that the Cluniacs, despite their success in other countries, never made much headway in Scotland. The only monasteries of the Order north of the Tweed were Paisley, Crossraguel and the little Abbey of Faill, in the parish of Tarbolton. Considerable portions of Crossraguel still exist, and at Paisley we have left to us the fine abbey church, though the remains of the domestic buildings have been in recent years ruthlessly and unnecessarily swept away. Faill is, I am afraid, best remembered by the old rhyme:—

The Monks of Faill
They made gude kail
On Fridays when they fasted,
And never wanted beef or ale
As long as their neighbours' lasted.

The rise and early history of the Order of Cluny are full of picturesque interest. By the irony of fate the body which a few centuries later was to become a by-word for pomp and luxury, was originally founded as a protest against the laxity into which monasticism had fallen in the tenth century. The founder was Guillaume le Pieux, Duke of Aquitaine, who, in 909, having decided to build and endow a monastery, set out with Bernon, the abbot of Baume-les-Messieurs in the Jura, to choose a suitable site. The duke and the abbot, travelling together, at last arrived at a spot so deserted that (as the chronicle says), "il semblait en quelque sort l'image de la solitude céleste." Bernon thought the place suitable, but Guillaume objected, pointing out that the monks would be subject to molestation from the hunters and their dogs tracking the game in the neighbouring forests. Bernon, however, brushed the objection aside, and told the duke to drive away the hunters, as there could be no comparison between the advantages of mere sport and the ultimate benefit he would derive from the prayers of the monks. This argument seems to have had great weight, and in the deed of gift the pious Guillaume sets forth very candidly his conviction that by his liberality he was materially helping to secure the future, not only of his own soul, but those of sundry of his kinsfolk as well. The conveyance included the domain of Cluny, farms, vineyards, forests, &c., not omitting "slaves of both sexes." The monastery was to be dedicated to SS. Peter and Paul, and was to follow the rule of St. Benedict. Bernon was nominated the first abbot, but after his death the monks were to have the right of choosing their own head. In accordance with a custom of the time, the deed concludes by an impassioned invocation of the punishments alike of Dathan and Abiram, Judas, Antiochus and Heliodorus upon the head of anyone who should contravene its provisions.

Bernon gathered together a little community of twelve monks and at once set about the erection of the monastery. St. Odo, who succeeded him as abbot, was, however, the real founder of the future greatness of Cluny. To him is due the initiation of the plan of establishing dependent communities of monks owning the authority of the parent abbey, and he succeeded in extending his sway over a number of monasteries in different districts of France and Italy.

St. Maieil and St. Odillon, the third and fourth abbots, worthily continued the work of St. Odo. St. Odillon especially wielded much influence, and was the trusted ally and friend of popes, emperors and kings alike. He added to and greatly improved the monastic buildings, and at the close of his reign was able to say (paraphrasing the words of Augustus) that he had found an abbey of wood and left behind him an abbey of marble.

But it was under St. Hugues, the successor of St. Odillon, that the Cluniac Order reached the zenith of its power and influence. St. Hugues had been in early life the intimate friend of the imperious and masterful Hildebrand, who, becoming Pope under the name of Gregory VII., is best remembered for

the haughty audacity with which he compelled even an emperor who had displeased him to stand waiting in the snow at the gates of his castle. The Pope did not forget his old comrade, and spared no effort to promote the prosperity of the Order of which the latter was the head. The wealth of the Cluniacs enormously increased. Fresh monasteries were founded in every part of Christendom, and older foundations were brought in under the sway of the abbot. But with all the power vested in him, St. Hugues was wise enough to see that it was judicious to consult from time to time the wishes of the community. Chapters-general were held, at which delegates from all the subordinate monasteries were present, and at these assemblies measures for the general good of the Order were brought forward and carefully considered.

The almost boundless charities dispensed by a great abbey like Cluny in the days of its glory afford alike an indication of the enormous wealth of the monastic orders and a proof of the liberality and benevolence of the monks. Udalric, in his "Antiquiores Consuetudines Cluniacensis Monasterii," mentions that, during the year in which he was writing, the benefactions of the abbey had been extended to 17,000 persons, and we may be certain that in the days of St. Hugues the charities of the Order were administered on a similarly generous scale.

We are too often apt to think of the monasteries only as they were in the days of their decadence, when wealth and luxury had in too many cases sapped their former usefulness, but we should never forget the invaluable services rendered to the world by the monastic orders at an earlier stage in their history. In feudal times, when the rude barons too often regarded the humane letters from the point of view of Archibald Bell-the-Cat, the abbeys were the only centres of light and culture. But apart from their services to education and apart from their benevolence and unstinted hospitality, we should bear in mind how much was due to the monks in reclaiming waste lands and turning barren stretches of moorland into vineyards and orchards and fertile fields. We should recollect that they were the first to recognise that the serf who tilled the soil was no mere chattel but a human being, and that while the great feudal lords ground their vassals to the earth with exactions of all kinds, the tenants of the abbeys were treated with kindness and consideration.

But I must return to St. Hugues. The Order of Cluny so increased under his wise and beneficent rule that the then-existing abbey church was found quite insufficient for the needs of the monastery. He accordingly decided to build a church more in consonance with the requirements of the time, and the great edifice which was so ruthlessly swept away was the result. When completed it excited such universal admiration that a legend arose that the plan had been given to Gauzon, the architect, in a dream by St. Peter himself. The church was in the form of a patriarchal cross—that is to say, it was cruciform, with a second or eastern transept. This arrangement is by no means uncommon in England, being found at Canterbury, Lincoln, Salisbury, Rochester, &c.; but in France the feature was unique. The architecture was, of course, Romanesque, the style in which all the great monastic churches of France are built. The nave was very lofty, and had double aisles. At the west end was a great narthex or vestibule, a feature characteristic of churches of the Cluniac Order, the best surviving example being found at Vézelay, in the Morvan. The form of the narthex varied. At Cluny it was an outer church with aisles. It has never been exactly ascertained what the purpose of these vestibules was, for while Viollet-le-Duc holds that they were intended for penitents, another, and to my mind a more plausible, theory is that they were for catechumens or proselytes, who were not allowed to enter the church. This is believed to have been the purpose served by the Galilee porches at Durham and Lincoln. The entrance doorway was ornamented by elaborate sculptures, similar to those still to be seen at Moissac. The length of the church, including the narthex, was 561 feet, 5 feet more than Winchester Cathedral, the longest church in England, a notable circumstance when it is borne in mind that English churches are specially remarkable for their great length, though they lag behind their French sisters in breadth and height. The breadth of the nave was 101 feet. A curious feature was the little chapel of St. Michael, suspended at the height of the aisle vaults between the narthex and the nave, supported by corbelling. The choir, with its richly-carved stalls, its frescoes and priceless tapestries, and its double *jube* or rood-screen, must in magnificence have hardly yielded to St. Denis itself. The tomb of St. Hugues occupied the centre of the sanctuary, which was surrounded by an ambulatory and five apsidal chapels, filled with splendid monuments. Three huge towers surmounted the great transept, while another stood at the centre of the eastern transept. Two smaller towers were placed at the entrance to the narthex.

The view of the abbey which opened to the eyes of the wayfaring pilgrim entering the fine double gateway (still happily in great measure spared to us) must have been very striking and imposing. On the one hand lay the abbot's

palace with its hanging garden, in front of him towered the great church standing on a raised parvis approached by five steps, in the other direction stretched away the long ranges of the domestic buildings, so extensive that at one time it is related there were gathered within the abbey walls Pope Innocent IV., St. Louis and his mother and sister, the Emperor of Constantinople, the princes of Aragon and Castile, the bishops of Senlis, Evreux and Langres, each of these personages being accompanied by a numerous suite, and yet the 400 monks were not put to the slightest inconvenience or interfered with in the use of their refectory or dormitories.

DUNBLANE CATHEDRAL.

A PARTY of members of the Dundee Institute of Architecture, Science and Art visited Dunblane Cathedral lately, when Dr. Rowand Anderson received them and explained the restoration which he has carried out. He pointed out at the outset that had it not been for the Marquis of Lothian the building would not have been in its present state. The Marquis, he said, was not a member of the Established Church, but he was sufficiently large-minded to take a broad view of everything that was for the good of his country. He appealed to the Queen and button-holed everybody who had any influence until he at last carried his project into effect. Proceeding, Dr. Anderson said the first thing he as the architect did was to get the building roofed in for the protection of the walls. In a discussion at a meeting of the Edinburgh Architectural Association the question of preservation *versus* restoration was raised. He maintained that the only way to preserve was to use the building for the purpose for which it was erected. They all knew the old saying, "An empty house is a bad tenant," and there was no doubt that had this work been delayed for a few years longer a series of violent storms would have made an end of it. The question was also raised that by the restoration of the cathedral one was destroying the picturesque character of Dunblane. He asserted that buildings were not erected for the purpose of forming studies for painters, but were put up for use. The church, he said, was not rich in monuments; possibly there were a good few of them, but they are nearly all gone. Amongst the more interesting monuments were the three blue stone slabs (lying within the choir), the matrices of brasses which had been placed there to the memory of Margaret Drummond and her sisters Euphemia (Lady Fleming) and Sybil Drummond, who came by a tragic end at Drummond Castle in 1502. With Margaret Drummond—who was described as a lady of rare perfections and singular beauty—James IV. fell deeply in love, and made her a promise of marriage. But for political reasons the nobles wished the young king to marry a daughter of Henry VII. (a woman who brought nothing but mischief and trouble to Scotland), and the clergy also forbade the alliance as being within the forbidden degree of consanguinity. As the king was obstinate, his mistress's death was resolved upon, and this was effected by means of poison mixed with food served up at a breakfast to which she had been invited by her two sisters. They perished with her, and the legend goes that they were carried to Dunblane and buried in the chancel of the cathedral. The brasses had been stolen, no doubt, for the value of the metal, and the Doctor thought the least the descendant of these ladies—the Earl of Ancaster—could do was to restore them. In answer to a query Dr. Anderson said there was no actual proof of this story, but it was a historical fact that they were buried in the choir at Dunblane. The founder's arch, he said, was discovered and restored in the north wall of the choir, and in it had been placed an effigy which tradition said was that of Bishop Dermoch, but which there was reason to believe was no other than that of Bishop Clement, the builder of the cathedral. Amongst the other effigies were those of a knight in armour and his lady. The knight was said to be the second Earl of Stratherne, who died in 1271; but the character of the armour and dress pointed to an earlier period, and he believed that the knight was no other than Gilbert, first Earl of Stratherne, who founded the See, and endowed it so richly in the early part of the thirteenth century. Subsequently Dr. Anderson led the way to the nave, where there is another sepulchral niche containing an effigy which is traditionally known as Bishop Ochiltree's, but the figure did not belong to the niche, as the feet had been cut away to make it fit. He also called attention to the beautiful screen dividing the choir from the nave, the elegant east window erected by John Stirling Maxwell of Pollock, Bart., and the chancel arch. Over this arch there is a double-arched opening, which has greatly puzzled experts. From the number of holes underneath the arches, it probably supported a gallery, although what that gallery was there for was unknown.

Dr. Anderson then led the way to the place used as a meeting-house in connection with the cathedral, branching off the choir, which he said was talked of as being the chapter-house. One member of the company remarked that it was

more like a lady chapel, and another suggested that it had possibly been used as a confessional. In reply to the first remark the Doctor answered "No," and said there was nothing of the nature of a confessional about it. He did not think there was such a thing existing in any church as a structural confessional. The confessionals were generally pieces of furniture. This concluded the inspection of the cathedral, and the company were then treated to some music on the grand organ by Miss Willison, Balhaldie House, Dunblane.

In proposing a vote of thanks to Dr. Anderson, Mr. Mackison, burgh surveyor, Dundee, president of the Society, said the restoration was one that Dr. Anderson had the greatest credit in, and he hoped it would lead to his name being associated with the restoration of other ancient edifices.

Dr. Anderson said it afforded him great pleasure to meet such an intellectual company, and he was also glad to see so many representatives of the fair sex present, because it was of great importance to architects that they should take an interest in architecture—they had so much say in it, and it was right and proper that they should be well instructed. The work in connection with the restoration of the building had been a very great pleasure to him, though it entailed a considerable amount of anxiety, for he had to be very patient at times. He was glad to say, however, that in the long run he had met with great sympathy and support from the members of the restoration committee in carrying out the work. Of course, they knew that the great bulk of the cost had been borne by an excellent good lady, Mrs. Wallace, of Glassingal; in fact, without her liberal support the work would never have been done. There was one thing he would like to point out, and that was that what had been done here showed what could be done elsewhere. Destruction and failure were prophesied here, but the prophecy had not been fulfilled. There were many other buildings throughout Scotland which ought to be dealt with in the same way, and restored to their original uses. Whatever had been done, he maintained that old Dunblane Cathedral was still here. He hoped the good example that had been set in Dunblane would be followed elsewhere, and that the many interesting buildings scattered over Scotland would not be allowed to disappear off the face of the earth. They could not afford to lose them, because they were as much a part of the history of their country as any written document. A country without a history was a very uninteresting place indeed, and the more of history they had the more attractive the country was to themselves. Then there was the lower aspect to take—commercially, it was an excellent thing for Scotland. They had descendants all over the world, and these descendants were men of intelligence who liked to come back to the old country, and having read of these places it was sad for them to come home and see them lying waste and going to ruin. Though that was the lower view to take—the commercial view, to bring money into the country—it was one of the great duties of the people of Scotland to preserve the records of the past.

EXPLORATION OF HADRIAN'S WALL.

THE following circular has just been issued by Professor H. F. Pelham, Mr. J. L. G. Mowat and Mr. F. Haverfield, all of Oxford:—No branch of Roman history has been studied with so much success during the last few years as the military system and frontiers of the Empire. In every quarter, on the Rhine and the Danube, in Africa, Egypt and Asia, excavations are being planned and discoveries made. In Germany the Imperial Government has lately established and subsidised a Commission to systematically examine the *limes* between Coblenz and Regensburg, and the work has already produced important results. It is now proposed to make further exploration of the best preserved and perhaps the most elaborate of all the Roman frontier lines, that which crosses northern England from the mouth of the Tyne to the Solway Firth. Much has been done to explore this frontier line. The life-long labours of Dr. Bruce were full of fruit, and ten years ago Professor Mommsen was able to say, in his account of Britain, that Hadrian's Wall was at that date the best known of all the Roman frontier defences. But the progress of inquiry has brought forward new problems, and further exploration seems necessary. In particular, it is desirable to examine the Vallum, the strange and solid earthwork which accompanies the Wall for almost all its length, and further to ascertain whether our Wall is attached to any gromatic ditch like that recently found in Germany. It might also be possible, with the consent of landlords, to explore one or two of the stone forts and fortresses of the Wall. For all such work the present is pre-eminently the time when other workers in other countries can interchange discoveries and lend mutual aid. The visit paid to the North of England last summer by General von Sarwey, military director of the Reichslimes Commission, showed how much such interchange of aid may profit. Fortunately the work is not only proposed, but begun. In Northumberland the Newcastle Society of Antiquaries dug

some sections in the Vallum last summer with very notable results, and the work is to be continued. The Cumberland Archaeological Society has voted 50% and appointed a small committee to select suitable sites and promote excavations along the western part of the Wall. We venture to appeal for subscriptions to be applied, according to need, to these good works.

TESSERÆ.

Rembrandt as a Colourist.

THERE is no doubt, for the colouring and chiaroscuro, Rembrandt is one of the most able artists that ever lived. Nothing can exceed the beauty, freshness and vigour of his tints. They have the same truth, high relish and sapidity as those of Titian. Indeed, they have the closest resemblance to the hues of Titian when he had Giorgione most in view. There is identically the same attention to the rilievo and force obtained by his strong shadows and low deep tones; and his chiaroscuro, though sometimes too artificial, is yet often (particularly in contracted subjects) productive of the most fascinating effects. It may be worth observing that no part of Rembrandt's excellence is derived from the loads of colour which he has employed, or from the obtrusive, licentious, slovenly conduct of his pencil, or his trowel, which he is said to have used. Whether he was originally led to this affectation by the uncertainty of painting without previous determination, or whether it was the mere affectation of differing from his contemporaries, who were generally solicitous about high finishing, matters not; but the practice ought to be avoided. If it had arisen, as it does in old Bassano, from an attention to the details of his objects, and was nowhere used but as these details called for it, it might appear the effect of a mastery and freedom which might plead its allowance; but in Rembrandt it is not less disgusting than it is useless, for although it may be true that the unpleasantness of the manner disappears at the proper distance for seeing the work, yet the effect of the picture at this distance has no advantage over a picture of his contemporaries, Jordaens or Vandyke, whose tints are equally true and precious with those of Rembrandt, but whose beautiful handling or manner of execution is much more compatible with all the other great concerns of art.

Greek Buildings.

A pure Greek building is a work of art cunningly, *i.e.* knowingly, devised, to which common sense furnished the ground-plan, a fine sense of proportion the elevation, and an exquisite perception of the beauty of curves the details. Every stone in it was the object of study on the part of the architect, and of patient labour on the part of the workman. Greek architecture has been chiefly reproached for uniformity in plan and elevation, a consequent want of the picturesque, and a repetition and want of variety in its details. Certainly in the temples, which are almost the only buildings with which we in England are acquainted, there is much sameness. It has been said, with a degree of truth, that all temples are alike. But, in justice to their designers, we must consider what were the requirements of Pagan worship: a dark naos or cella, for the reception of the statue of the divinity; a pronaos or antechamber, to receive the statues of great men; an opisthonaos, to contain the offerings at the shrine and the vessels required for sacrifices. What could answer these requirements better than a dipteral or pseudo-dipteral temple? To have departed from simplicity in plan and elevation, by throwing out projections or carrying up towers for the sake of effect, would have been a departure from the two great principles of common sense and economy (to use the word in its widest signification), both of which ought to guide architects at all periods of their art. So much for the temples, to which naos and pronaos were as essential as nave and chancel to a Gothic church. But when we come to other buildings, such as gymnasia, thermæ and such like, and the edifices within the temenos of the temple, we shall find that they were arranged as convenience required, and with a certain regard for the production of a picturesque effect. The grouping of Greek buildings is eminently picturesque. Any one who has not visited the Acropolis of Athens will perceive this by looking at a good view of it in which the buildings are restored. By the side of the noble flight of steps leading to the Propylæa, the beautiful little Temple of Wingless Victory juts out at an angle with the building above it. The bases of the Propylæa, the Parthenon and the Erechtheum are in different planes, and they combine with the irregular distance in which they stand to form a most picturesque grouping, which seems to be studied instead of fortuitous. Take again the city of Priene, built upon the lowest spur of a magnificent mountain, its lower walls washed by the sea, its higher walls climbing the mountain side, its stadium, gymnasium and agora towering one above the other in an irregular manner beyond them, the massive terrace, with the Temple of Minerva Polius at one end of it, and, above all, a precipice some 600 feet high, crowned by the Acropolis. These

various masses of buildings, arranged as they are without the advantages of such a magnificent site, would form as fine a picture as the cathedral, campo santo, baptistery and belfry of Pisa. The Greek architect made the best of the materials at his disposal, as far as his imperfect knowledge permitted; he built after a certain system of proportion; he studied the minutest details, and designed mouldings to suit their various positions; and finally made use of many refinements to improve the perspective effect. A pure Greek building is a model of sound construction, built generally upon a rocky site, hollowed to receive them; the foundations of the platform consist of various blocks of rough stone, laid alternately, transversely and longitudinally, and cramped together. If the stylobate is of unusual height cross walls bound the foundations of columns with those of the cella and with one another, the intermedial spaces being filled with smaller stones well compacted. This was the case in the Temple of Apollo Smintheus. Upon this foundation were laid the steps and pavement of the precious white marble brought from Paros or Cyzicus. The plinths of the columns were frequently placed in slight sinkings in the pavement. The drums were united by dowels of bronze. The walls of the cella were so well worked and closely laid that the joints are imperceptible. These and the architrave stones, friezes, cornices, transverse beams and lacunaria were so strongly joined together by means of cramps run with lead that the whole formed almost a solid mass, which the earthquakes of 2,000 years and the violence of men leaves only partly rent in sunder.

Giulio Romano as an Architect.

The architecture of Giulio is markedly different from that of everyone else. He strongly affected square forms, and seems to have laboured as much as possible to divide his buildings into square, or nearly square, compartments. The recipe does not appear very promising, and yet the Palazzo Cenci, as it was once called (or Palazzo Maccarani), in spite of dilapidation, is a noble design. Giulio may be considered as the last of the Roman architects. Their style is marked by a severity which some critics prefer to the grace and beauty of the Palladian. They followed a beau ideal of a higher character and expression, although Palladio undoubtedly reached his object much more nearly than any of the Roman architects. Had Raphael lived and followed architecture, something far superior might have been attained, but he could hardly have done more for the Roman style than Palladio did for that which he pursued.

Poetry in Art.

It has been very truly as well as elegantly said by Ovid that Venus would have for ever remained buried under the waters if she had not been happily drawn out by the pencil of the ingenious Apelles. And indeed, everything considered, it would be very difficult to divine in what state, and to what degree, the whole or any part of the sublime imagery of the Greek and Latin poets could be communicated to their readers if these matters had not been thus realised to our eyes in the works of art which fortunately remain. Words after all are but words, and there is no peculiar art in poetry which can make them anything more. They are but symbols formed for the eye out of twenty-four arbitrary scratches called letters, and certain vibrations of the air, occasioning certain irritations in our organ of hearing, which by national compacts are made to suggest the idea of existing things, with their several modes and degrees of relation. And though the communication of all this matter of compact is more or less perfect according to the degrees of our education in it, yet how very imperfect it is, even at the best, will soon appear on attempting to describe in mere words any individual complex forms, as the portrait or likeness of any man's face, and numberless other matters which need not be mentioned. However, what language wants in precision is abundantly compensated in the facility and extent of what it does communicate in the whole range of characters, passions, sentiments and intercourse of society. But this facility, extent and use of language, applied as it is to all arts, sciences, trades and other objects of human concern and knowledge, is common, and more or less every man's inheritance, and Malebranche, in his "Inquiry," and Nicole, in his "Essais de Morale," Swift, Cervantes, Sterne and many other prose writers have at least as deeply and extensively applied this language as any of the writers in verse, whether of the comic, tragic or epic kind. It should seem then that the advocates for the superiority of poetry over painting have been contending for advantages which are by no means peculiar to poetry, and a stickler for Cocker's arithmetic might as well contend for the superiority of his own art, since there are many numerical combinations about which the art of painting would be employed to little purpose. Let us suppose for a moment that a great artist, a Michel Angelo, a Raphael, Poussin or Rubens, was deprived of his sight; his art would then be utterly lost to the world. He would no longer have it in his power to hold out that mirror of ingenuity, where the whole visible creation is magically portrayed with so many accumu-

lated advantages, where all its beauties are united and all its deficiencies, imperfections and incongruities taken away. Yet, notwithstanding all this, if you will allow him the use of language, he has it still in his power to talk of all these things, and whether this talk be delivered in prose or verse, whether it be sung or said with more or less energy, you have still remaining all that poetry can give, which, as was observed before, is only an animated account of certain productions of this master art, this improving mirror of nature, which his blindness debars him from calling into actual existence. Hence, then, we are warranted to conclude that fine art may, to use a French phrase, be justly termed "L'art par excellence."

Composition of the "Laocoon."

Whatever be the main scope of the subject, and whatever materials it may with propriety afford, whether of the simple, pathetic, or heroic and sublime kind, the first and chief attention of the composition should be to dispose such materials in the manner best calculated to enforce and ennoble this main scope or end, which the subject proposes, and to reject or carry into the parts of least consequence whatever does not contribute to this end. For example, in the subject of *Laocoon* the principal aim of the artists should be (as it has been) to impress upon the mind of the spectator those emotions of terror and pity which must arise from that climax of distress exhibited in the unavailing efforts of an agonising father and his children, the children calling upon the father for assistance, and he upon Heaven, that has abandoned him to his fate. A second consideration of interest, and which greatly enforces the first, is the graceful, beautiful forms of the children and the noble, vigorous, athletic figure of the father, which is admirably calculated to exhibit those convulsed gripings which agitate every part. If, agreeably to the absurd wishes of some shallow critics, these sons of Laocoon had been of the same soft, pulpy texture as the children of Fiamingo, besides being fitter for the nursery than as attendants upon the altar, their little bladder-like forms would have been incapable of discovering any interior agitation. It may be further observed that were these figures encumbered with drapery it could have no relation to the main end: it would then be occupying space to no purpose, or, what is worse, to a bad purpose, as it must divert or divide the attention to inanimate things foreign to the main end, and interrupt the unity of this expression of agony and distress, which should be pursued throughout. Besides the variety arising from the different ages and characters of these figures, their actions and positions are so diversified that in every view of this admirable group the eye is presented with a combination of circumstances and aspects so beautifully varied from each other that it is difficult to say which is the most to be admired, the vehement, direct and uniform address of the subject, or the graceful and skilfully-variegated manner in which it is communicated. Pietro da Cortona has treated this subject upon quite other principles. Blind as he was to all its grandeur, pathos and real excellence, his composition was, as usual, thrown away upon what is in many cases mistakenly called the picturesque arrangement of heights and distances, lines, angles and other mechanical subordinate attentions, which may be of prime consequence in trifling subjects, but which in such cases as the present should never be sought after but as aids and agreeable attendants upon those matters of higher consideration which never enter the thoughts of unfeeling and mere mechanical fabricators of composition. Such men do but disgrace themselves in great subjects. The matters of art are suited to all capacities when artists know how to make a prudent choice; from still life upwards every man might find something of a piece with himself.

Flat Washes.

There are certain difficulties in the management of water-colours which must be surmounted and methods of practice in manual operation to be acquired before the learner can hope to make any progress. He who without method will begin to make his efforts at random, and hardly knowing what he intends to do, must necessarily fail, for although many parts of a work of art may in some measure be subject to accidents, of which advantage may be taken by a master, yet the whole can never be produced by chance or be formed by a combination of such accidents. The first of these experienced by a beginner is spreading a breadth of any colour with any equal strength of tint, and of laying it so as to produce the desired or intended form. In the first operation, that of making an equal wash with any colour, the following precautions are to be used:—(1) The colour must be mixed of an equal tint, and in a sufficient quantity to cover the given space, so as not to require any alteration during the operation. In these trials India ink or sepia may be substituted for colour. (2) It should be diluted until it is sufficiently fluid to flow freely from the pencil, and to be distributed readily upon the paper, in doing which a large pencil is to be preferred, as it will contain more of the colour and keep it more equally moist than a smaller one will do. (3) The paper should be held with a moderate degree of

inclination by placing the drawing-board on the lap, with the upper part leaning against the easel or a table; then beginning at the upper part and descending the colour will run downward and settle equally. (4) In order that it may do so the pencil ought not to be used with too much haste or be carried over the paper faster than the colour will follow it, the readiness to do which will depend upon the inclination of the surface. The learner will soon discover that to cause this equality it is requisite that the whole of the space covered should be equally wetted with the colour as possible. In the first attempts he will probably continue to drive it until the pencil is exhausted, and by neglecting too long to supply it the part where the addition is made will be unequal, in consequence of its being more wet than that it was joined to. The attraction between parts of the same or of different colours, according to their different degrees of moisture, being the principal cause of that inequality of tint the learner finds it difficult to avoid, he ought to observe how it acts and use the means to prevent its recurrence. He may observe that in a breadth of colour if from delay in spreading it or any other cause one part is beginning to dry while another in contact with it continues quite wet, the drier part will attract the more fluid colour until it is prevented by too great a degree of dryness from conducting it further. Where it stops a streak will be formed of unequal tint, and darker than any other part of the space. For this reason the colour should not be unnecessarily worked about by the pencil in a space already covered with it, as it will by that means be continued wet there when the edges and extreme parts are beginning to dry. This should be carefully attended to, being that which renders the practice of painting in water-colours in some respects more difficult than painting in oil, the latter allowing time enough for every operation. When it is required to lay the colour so as to produce certain forms these should be well considered, to avoid any alteration, if possible, during the operation. For the reasons before assigned the colour should be spread as speedily as possible and without needless alteration of the form or attempt to rectify what is carelessly done by a touch or dash equally careless and at random. When the form is expressed the sooner it is left the better; working upon it longer than while the colour continues sufficiently fluid to spread freely will cause muddiness and inequality of tint. Any required alteration may be best made after the part has been dried with the same tint, extending it carefully into the desired form. This should be done with little colour in the pencil, and neatly joined to the part to which it is added; the least touch of the colour over what was done before will form a dark place, making the additional part appear as a patch, which should be carefully avoided. A gradation of tint, or what is called "softening off," may be made in extending the colour by touching upon its edge with the pencil and water only; by keeping in readiness another large and clean pencil to apply the water the operation will be facilitated. This will attract the colour and cause it to descend and spread upon the part so wetted.

Use of Timber.

To obtain the greatest strength in timber beams, joists, rafters and bresssummers, the depth must greatly exceed the width—the greatest strength opposed to the greatest strain. A joist 6 by 3 will bear twice as much if put edgewise as it would if laid flat. If the weight to be supported be in proportion to the length, then, the width remaining the same, the square of the depth divided by the square of the length ought to be the same also, *i.e.* the depth of a joist ought to be in direct proportion to the length, and for stiffness the width proportionate to the depth. Where the question is of a piece of timber supporting itself, the weight is as the length multiplied by the depth, and we must multiply this again by the length for a divisor. A rod of fir inch square, or a plank 10 by 1 laid flatwise, would keep quite straight with a bearing of 5 feet. A piece of timber 10 inches square would swag very much with a bearing of 50 feet.

Greek and Roman Theatres.

The stage of a Roman theatre was much broader and deeper than that of a Greek theatre. The passages leading at each side from the stage to the orchestra were arched over to make room for more seats in the Roman theatre, and there was a flight of steps in the middle of the auditorium where in the Greek theatre there was a block of seats. Outside, however, there was a greater difference between a Roman theatre and a Greek theatre. It had been impossible for the Greeks with their columns and beams to make a great auditorium on level ground, because such great masses of stone could not be supported by columns and beams. They therefore generally placed theatres in the trough of a valley or on the side of a hill which could be hollowed into a semicircle, making the rows of seats in the natural rock or earth, with but little artificial assistance. The Romans could employ arching, which carried far more weight, and could therefore build their theatres on level ground, with a semicircular wall for the outside of the auditorium ornamented after a new fashion.

NOTES AND COMMENTS.

LOSSES through deprivation of amenities are generally difficult to estimate when valuing property, especially when the enjoyment is only occasional. A claim and subsequent assessment of the kind were the cause of setting aside the verdict of a jury which otherwise would be considered as well founded. The case came on appeal before the Queen's Bench Division on Monday. The London School Board, under the Lands Clauses Acts, took possession compulsorily of a solicitor's house and office at Greenwich. The house was held on lease, of which thirteen years were unexpired, at a rent of 40*l.* per annum. The solicitor claimed 250*l.* for the lease and 1,500*l.* for loss of business, &c. There was also a claim for his loss of access to the Thames, which, as we have said, became the vulnerable point of the case. As the solicitor was able to secure offices in the same street, he was willing to have his claim for loss of business reduced. An inquisition was held, and the sub-sheriff, in putting the case to the jury, divided the claim as follows:—"First, there is the leasehold interest in the old premises. Then there is the 25*l.* for the removal and readjusting his office. Then there is the question of his being disturbed in his business as a solicitor, whatever you think it right to give upon that question, and then there is, further, the loss of amenities and enjoyment of his old premises, for which you should give him something, if you can find in money what will compensate him." The jury awarded 563*l.* It was not stated whether that sum included a farthing on account of the deprivation of access to the river, but that such an item was put before them was sufficient to authorise the School Board to apply for a *certiorari* to have the verdict quashed. On Monday the rule was made absolute. Mr. Justice CAVE held that compensation for loss of access to the river was included in the sum given for the leasehold interest in the premises, and it could not be given twice over. As it was impossible to distinguish how much was allowed for amenity, the verdict must be quashed. Mr. Justice COLLINS also considered there was no alternative but quashing. It is more than likely that the jury took the same view as the two judges, that the access to the river was an interest of which they could not reckon the value; but as there was nothing to indicate whether that was the case, the claimant has had to suffer.

THE position that is assumed by the Royal Academicians in dealing with lithography is inexplicable. There is a "Black-and-White Room" in the Academy, to which drawings in crayons on paper are admitted. Why should impressions of similar drawings on stone be rejected, especially when impressions from wood-blocks, steel and copperplates are welcomed? The French place lithography on a level with engraving in their exhibitions, and not only are lithographic plates shown on the same walls as etchings or engravings, but they are also eligible for winning the medals and "mentions honorables." But then the French are aware that lithography is most difficult work, which Academicians from DELACROIX to FRANÇAIS have undertaken in order to display their skill, and in the ateliers of the foremost painters lithographic stones are to be seen. The majority of our English Academicians have neither the skill in drawing nor the precision of touch which is required for the work, and naturally they undervalue what they cannot undertake. Lithography is therefore treated like photography. The academic mind regards it as one of those arts to which this year's motto on the title-page of the catalogue applies:—"It is only the disease of the unskilful to think rude things greater than polished." Lithography when vigorous is probably thought to be rude, and a pictorial plate cannot well be produced from a stone if it is polished. But REMBRANDT would not have considered the facilities which a "grained" stone offered for expressing chiaroscuro as inadmissible, and there is no country in the world where the art is treated with the contempt which it receives in England. That, of course, arises from the example given by the Royal Academicians, who have their own peculiar reasons for standing apart from a process which is as merciless as fresco in revealing the weakness of incompetent people when they meddle

with it. Lithography has, we admit, one disadvantage. It is a modern art which was applied from its origin to business purposes. But if that objection helps to make it obnoxious in Burlington House, the Academicians should also consider that the arts which they represent have been also utilised as aids by traders.

GERMANY is proud of its contributions to the Chicago World's Fair. It was therefore to be expected that a record of the department should appear. We have the first volume, which is brought out by the Bavarian Society of Art Industry, under the direction of Professor GMELIN, and published by M. SCHORSS, of Munich. In addition to the blocks in the descriptive introduction there are fifty-six large plates representing examples of many kinds of "Kunstgewerbe." The skill of the Munich draughtsmen and photographers is everywhere known, and it would not be easy to discover an example of an exhibition catalogue which surpasses Professor GMELIN'S. The designs are characteristic. In all we find a surprising strength and accuracy. The Germans are glad to exhibit a national pride by treating Gothic and Renaissance types after the manner of their predecessors. The ornament therefore appeals to one of their countrymen more closely than to a stranger. But everybody can appreciate the precision of lines and contours, however small, and the knowledge shown in the disposition of ornament. Signs of thorough drilling are evident everywhere, as well as respect for tradition. Is it in revolt against the national love of discipline that so many examples of rococo are produced? At one time, when French ideals were set up for imitation by kings and princes, the style (if it can be called by that term) might be supposed to be delightful and expressive by courtiers, but as those days have passed away rococo should be made to follow them. The German mind has not the frivolity that is necessary when lines are to be turned in wrong directions at unexpected moments, and German fingers are too strong for the fantastic tricks that are only excusable by their nimbleness. It will be said that in Germany work has to be turned out to suit all the markets of the world, and as long as carved and gilded rococo finds many purchasers it must be designed and carved. That excuse does not explain the admiration it receives, and which we believe is a relic of an old belief that fettered the genius of the land in order that rulers might be gratified.

THE works that are submitted every year in order to compete for the prizes offered by the Académie Française are generally varied. This year M. E. BERTRAND has been awarded 1,000 francs for his book on "Painting and Art Criticism in Antiquity." M. LEMONNIER has gained a similar sum by his volume on "French Art in the Time of Mazarin and Richelieu." The name of ROBERT BURNS is not unknown in the Academy, and, owing probably to the absence of novelty, M. ANGELLIER was rewarded with only 500 francs for his "Robert Burns, his Life and Works." A prize of the same amount was given to M. RODOCANACHI for his "Workmen's Corporations in Rome from the Fall of the Roman Empire." "A History of Roman Eloquence from the Death of Cicero to the Accession of Hadrian" was better adapted to please the judges, and the author, M. VICTOR CUCHEVAL, accordingly received 1,000 francs. The principal advantage of winning one of the prizes is the effect it produces in increasing the sale of the recipient's books.

MESSRS. W. & G. AUDSLEY, now of New York, have commenced proceedings against the New York Municipal Building Commission for damages on account of the loss sustained by being deprived of their designs and hindered from winning prizes by the inaction of the Commission. According to the conditions of the competition, six designs were selected for special consideration out of the 194 sent in nine months ago. But no decision was made about one of them being suitable for adoption, and meanwhile the whole of the plans are retained.

SCHOOL BOARD OFFICES, READING.

WE reproduce this week a perspective sketch of the new offices recently erected by the Reading School Board. The new building is in a central position, and contains the following accommodation:—On the ground floor—clerks' offices, accountant's offices, committee-room and attendance officer's office, with waiting-room and separate side entrance. On the first floor—board-room, the clerk's private office, committee-room and lavatories. On the basement—caretaker's quarters and heating chamber. The building is of local red brick, with Douling stone dressings. The work has been very satisfactorily carried out by Mr. THOMAS PILGRIM, builder, of Reading, from the designs and under the superintendence of Messrs. CHAS. SMITH & SON, architects, of Reading, Mr. GEORGE being the clerk of works.

HOUSE AT WREXHAM.

THIS house, which has been erected for Dr. E. D. EVANS, is situated at the corner of Egerton and Lord Street, having main entrance from Egerton Street, and is built in Ruabon brick with terra-cotta and Cefn stone dressings. It contains on the ground-floor breakfast, drawing and dining-rooms, kitchen, pantry, scullery, &c., with side entrance for patients, giving access to waiting-room, consulting-room and surgery. On the first-floor are nursery, five bedrooms, lavatory, bath-room and conveniences, with attics over. In the rear are the stable buildings, comprising two-stall stable, loose-box, harness-room, coach-house with loft over, also wash-house, coals and other conveniences. Mr. GETHIN, of Shrewsbury, is the builder, from plans and specifications prepared under supervision of Mr. T. G. WILLIAMS, M.S.A., 3 Cable Street, Liverpool.

BALLARD, COOMBE WARREN, SURREY.

BALLARD is the name of a large house erected at Coombe Warren, near Kingston-on-Thames, in 1873, for Mr. EDGAR, from designs by Messrs. F. & H. FRANCIS, architects. It was purchased in 1884 by Captain LEE GUINNESS, of Dublin, who erected a new wing, coach-houses and stabling, and other extensive additions, increasing the original length or frontage of the house, &c., from 200 feet to 400 feet. The new additions, stabling and lodge were erected from the designs of Mr. W. F. POTTER, architect, of 8 York Grove, Queen's Road, Hatcham, and are faced with red bricks and Portland stone dressings. The stable fittings were supplied by the St. Pancras Ironworks Company. Our illustration is a perspective view of the entrance lodge.

THE PHILÆ TEMPLES.*

THE proposal to raise the temples of Philæ I consider a question of great archaeological interest, as any attempt in this direction is certain to end in the ruin of these interesting remains. When the Egyptian Government engineers found that a reservoir on the Philæ site would submerge the Philæ ruins, they proposed to raise them, and included a sum of 200,000*l.* for this purpose in their estimates. A writer in the May issue of the *Nineteenth Century* considers that it would be far easier to raise them bodily than any of the buildings he has seen so dealt with in America. I beg to differ from him and maintain that the two problems are quite different, and the conditions totally dissimilar. A modern building is tied together by iron and wood; these are absent in an Egyptian temple. Modern walls are bound together by elastic adhesive materials; the old Egyptian work was laid dry. The cross section of a modern wall bears so small a proportion to its length that the elevating screws used for this sort of work can be readily applied in a definite direction and actuated from both faces, with the workmen in sight, under control and in hearing of the signal by which they work. This would not be the case in the propylon of Philæ, which is 22 feet wide at the base; more than half the workmen employed in lifting such a mass would be underground and out of control. Again, in the

modern building the loads on the foundations are fairly uniform, which admits of easy apportioning of the power to the weights to be raised. In a temple there are quite different conditions; the intensities of the loads for contiguous parts would vary constantly, so that I doubt the possibility of calculating them with sufficient correctness to insure uniform upward movement; this would mean fracture and failure of the operation. I never heard of a colonnade or of an arcade having been lifted by elevating screws. It would not be an easy matter to lift one that is in good condition by this means; a ruined one would be thrown down. All the parts of the temple would have to rise simultaneously, so that every wall would have to be prepared for lifting at one time. To get the shoring in and the elevators under the walls costly blasting in granite would have to be undertaken, to a depth of at least 4 feet under the walls and under the pylons. Miners would have to be imported from Italy or Trieste, as they could not be obtained locally, quarrying on a large scale having ceased in Egypt since the closing of the quarries near Alexandria, on the completion of the Port Said and Alexandria breakwaters and the Alexandria mole and harbour works.

The writer mentioned suggests that advantage be taken of the military precision of the garrison of Assouan to work the elevating screws; it is almost certain that they would not be permitted to perform work of this nature. It is also probable that they are not in sufficient numbers to do more than raise the temple piecemeal. The strength of this garrison is reckoned to be about 1,000 men. I estimate that the great propylon of Philæ cannot weigh less than 8,500 tons; using elevators capable of lifting 10 tons each, 850 men would be required to work them—the small inner propylon would require 250 men, or a total of 1,100 men. Elevators capable of raising 20 tons each would take more than half the garrison. The area of the propylæa is about one-ninth of the total area of the temple; 450 men would not suffice to manipulate the elevators required for the remaining eight-ninths. If the latter description were used they would probably have to be specially made; there would seem to be very little demand for appliances of this power, as only one English maker includes them in his trade catalogue. Hydraulic elevators could not be used, as their delicate valves would soon fill with sand.

It is said that the different parts of the temples (stone for stone) will occupy the same relative positions to one another after raising as now, except for the difference of level; it must, therefore, be contemplated to raise the whole island 40 feet. The island measures 417 yards by 135 yards; 836,000 cubic yards of material would be required to make up the difference of the level; the weight of this would not be less than 775,000 tons, and might exceed 1,000,000 tons, according to the description of material used. The whole of it will have to be obtained from one bank or the other of the river at great cost. If the temples can be raised they would stand on 40 feet of made ground instead of on solid rock as at present. This would complete their ruin in a very short time unless underpinning were resorted to; every building on the island would have to be treated in the same way.

It might be interesting to calculate the approximate amount of underpinning required and the probable cost, say, for the Temple of Isis. To make a thoroughly sound work of it a solid platform should be constructed under the whole, except the court behind the great propylon. I make this area equal to 24,134 superficial feet, the content equal to 965,360 cubic feet; at the Cairo rate of 2*s.* 5*d.* per foot cube for hard stone, roughly scabbled from quarry, in Portland cement, the cost monies out at 126,647*l.*, a very large proportion of the 200,000*l.* estimated. Although the estimate of 200,000*l.* is a large one, it may easily be exceeded. He must surely underrate their beauty in saying that the wonder excited arises from the magnitude of the masses handled by the ancient Egyptians, rather than from the merit of their works.

I have always understood that all visitors to the place—except perhaps one—are agreed that the scene of which Philæ forms such an integral part is the finest in Egypt, and that it compares favourably with all the famous scenes of the world. There must be some particular charm about it to produce such a consensus of opinion. I believe the explanation to be found in the fact that the temples at their present level harmonise so perfectly in scale, arrangement and position with the surroundings. The multi-axial setting out of the plan of the Temple of Isis gives to the elevation a play of light and shade exactly suited to the clear atmosphere and strong sunshine of Upper Egypt. I believe that any alteration in the present levels would destroy this artistic balance. I think archaeologists will agree with me, that from an archaeological point of view the temples would be valueless were they raised. It has also been suggested to rebuild the temples at a distance from the river bank and above the flood level of the reservoir. I do not think this need be discussed as the proposal cannot be seriously meant.

The origin of the reservoir schemes is so intimately bound up with the system of the irrigation of Egypt, that a descrip-

* A paper read at the meeting of the Society of Architects on June 12, by Major F. Seymour Leslie, R.E.

tion of the latter is necessary to a correct understanding of the former; in the same way the water supply of Egypt is so completely controlled by certain peculiar features of the Nile, that it will be necessary to also include these in the description. So as to keep within the time allowance, I shall limit myself to a general account.

The Nile, ranking among the first rivers of the world in length and catchment basin, has the least discharge, owing to the very dry and sandy region through which its central and lower part flows. It drains nearly the whole of north-eastern Africa. Its most important tributary, the White Nile, has its sources far south of the Equator, and after a course of over 2,200 miles to Khartoum joins the main stream, the point of junction being 1,864 miles distant from the sea. Lake Victoria, at an elevation of 3,574 feet above the sea, is the Nile's chief reservoir; it is on the Equator, and in the region of perpetual rains. After crossing the Ibrahimieh swamp, the White Nile enters Lake Albert, its second reservoir, at its north-east corner; there is a difference of level of 1,640 feet between the two lakes, Lake Albert being the lower of the two. Between Gondokoro and the mouths of the Gazelle river, a distance of 435 miles, occurs the region of living dams of vegetation, which completely block the river and regulate it during flood. Between Lake Albert and the junction of the Sobat, at a distance of 2,261 miles from the sea, many important tributaries join the White Nile; the Sobat itself is the most important of them all, having a discharge equal to that of the White Nile. The occasional drying-up in summer of this stream results in a low Nile in Lower Egypt. This branch of the Nile obtains the name White from the admixture of the waters of the Sobat, which carry down a whitish clay; above the junction they are green and slimy, with decomposing swamp vegetation. The Blue Nile should be considered the true Nile, for its flood brings down the rich volcanic mud which it has deposited during many ages in the Nile valley, converting sandy wastes into one of the most fruitful countries of the world. I have never heard an explanation of the name Blue, as applied to it; it may refer to its appearance when not in flood, as it is then comparatively clear.

A few miles south of Berber the Nile is joined by its last tributary, the Atbara, a torrential stream issuing from the Abyssinian mountains. From their confluence to the sea, a distance of 1,677 miles, the Nile flows alone, without any addition to its volume, and by human agency the Nile at this part of its course is made to part with its waters for the fructification of the soil of Egypt. About sixty miles north of Khartoum is the sixth cataract, the first of the series of rapids that ends with the first cataract. They divide the river, for a length of 1,236 miles, into alternate stretches of broken water and long deep reaches of comparatively smooth water. Both the rocky beds of the rapids and the deep reaches assist in retarding and regulating the flood. At Cairo, 110 miles from the sea, is the apex of the great deltaic formation of Lower Egypt; the Nile here divides into two branches, the Rosetta branch and the Damietta; these are the only two of the ancient seven that have not silted up and disappeared entirely. In past ages the Nile repeatedly overflowed its banks, and by deposits of mud formed mounds parallel to its course, which gradually slope away towards the desert. These mounds had an important effect in determining the particular system of irrigation adopted by the ancient Egyptians, for, had they been absent, this system would have been impossible. The last physical feature to state in connection with the Nile, viz. the annual flood or inundation, is the most important of them all, for without it Egypt could never have been an agricultural country. The heavy rains in the valley of the White Nile begin in April, and force down the unwholesome green stagnant water of the swamp regions. The time of the arrival of this water in Cairo varies from June 10 to July 10, according to whether the rise is late or early. The red muddy water of the Blue Nile follows from ten to twenty days afterwards, the rain beginning in Abyssinia about the middle of May.

The Atbara takes a month to saturate the desert and its own dry sandy bed; it then comes down in great volume, so that the rise of the Nile is rapid immediately after the appearance of the red water. At the beginning of the flood it takes twenty-five days to travel from Khartoum to Assouan, and twelve days from Assouan to the barrages at Cairo. At full flood these periods are respectively thirteen days and six days. The rains in Abyssinia cease about September 15, and the rivers, being of the nature of torrents, are the first to fall. The Nile reaches a maximum at Assouan about September 5, the maximum in Lower Egypt is generally about October 10; it would be at its highest about September 11 were the rise not retarded by the filling of the irrigation basins in Upper Egypt in August and September. They are not emptied and the water returned to the Nile until October.

The ancient Egyptians took skilful advantage of these different conditions to devise and carry out a very simple and effective system of irrigation that has been in operation for several thousand years down to the present time. It is known

as the basin system; to put it shortly, it consists in mapping out the land in terraced basins, separated from one another by lateral dykes. The levels above the sea of these terraces decrease in the direction of the flow of the river. The flood is admitted by cuts in the river bank, and passed on to a certain number of contiguous basins by similar cuts in the lateral dykes, filling the basins with even sheets of shallow water; it is then allowed to settle and deposit its mud, after which it is passed into a drainage canal, from which it flows back again into the Nile at a lower level than the district served by the drainage canal. This system was supplemented to a certain extent in Middle Egypt, and to a greater extent in Lower Egypt by shallow flood canals. Mohammed Ali, 1805 to 1849, made radical alterations in the irrigation of Lower Egypt; he destroyed most of the basin dykes, cut out deep summer canals on new lines and deepened some of the canals on old lines, with a view of producing summer crops of cotton. The experiment was not entirely successful; these deep canals ran shallow in flood, inundating the lands round the escapes, putting them out of cultivation. Some of them remain in that state now. An attempt was made to rectify this evil by constructing regulators; the canals then silted up between them and had to be kept open by expensive dredging.

In 1843 Mohammed Ali commenced the construction of the barrages or open dams across the two branches of the Nile at the bifurcation, with the view of maintaining a high-water level during summer for the feed canals of the Delta, whose heads are above the barrages. Owing to a faulty detail of construction and to settlements, they never operated successfully until quite recently, after extensive repairs. It is interesting to note a coincidence between the construction of the barrages and the proposed Philæ reservoir. Mohammed Ali ordered the demolition of the Pyramids to obtain stone for his works, but was persuaded to abandon the idea by a French engineer. We are proposing to virtually destroy Philæ, and another Frenchman, viz. the French commissioner, protests and condemns a reservoir at this place on account of the temples. Before we leave Mohammed Ali I will relate a tradition about him which I believe to be unrecorded—it was told to me by an Alexandrian boatman. This potentate one day witnessed an altercation between a butcher and a poor man. The latter complained that he had been given short weight, his complaint was found to be just, and the Viceroy caused one of his attendants to take the butcher's knife and cut strips of flesh off him, which were put into the scales until they balanced. From the foregoing account of the barrages, a reservoir in Upper Egypt would have been imperative as long as the barrages were unable to perform the functions for which they were designed, for the water passed into the river from the reservoir would not have risen high enough to enter the Lower Egypt canals. The repairs to barrages and the idea of a reservoir in Upper Egypt seem to have been concurrent; and Mr. Cope-Whitehouse initiated the reservoir schemes by discovering the Wady-Raian depression about 1886, and by formulating a project for a reservoir in it. His proposal was not favourably received by the Egyptian Government. The engineers of the irrigation department then proceeded to examine the course of the Nile with the view of constructing a dam in its bed. They found three suitable situations; the preference was given to one near the first cataract at Assouan. When it transpired that the island of Philæ would be submerged in the reservoir, the raising of the temples was proposed, with an alternative suggestion to rebuild them on the river bank.

Of the four situations proposed for the reservoir, the Wady-Raian is the most romantic, as it would provide a regulator in the neighbourhood of all that now remains of the ancient Lake Mœris, and the condition of Egypt in this respect, prior to the time of Amenemhat I., about B.C. 2466, might thus be restored. He is the earliest king of whom we have any record in connection with the Fayoum. He appears to have carried on reclamation works in this district, and the mounds of earth in the neighbourhood of the temple of Medinet-el-Fayoum may be fragments of his dyke. There is strong evidence that the Fayoum depression was Lake Mœris. Its formation is credited to Amenemhat III., 2300 B.C., but there are stratigraphical and other geological indications that both the Fayoum and the adjoining Wady-Raian depressions are natural formations, and that a movement of upheaval may have severed, or partly severed, the connection between the former and the Nile. One of the early kings may have restored this connection, and made the canal mentioned by Herodotus. Herodotus also records that the lake was artificially excavated, and that the spoil was thrown into the Nile and dispersed by that river; he also says that without difficulty he was led to believe this explanation of the absence of earth banks, as he knew by report that burglars had broken into a treasury at Nineveh by tunnelling, and disposed of the material excavated by throwing it into the Tigris. He lost sight of the fact that the latter was a simple mining operation and that the former meant mining 65,400 million cubic yards, thirty-one miles. This account is interesting, as showing that.

ancient travellers were as gullible, or as fond of improbable accounts of the wonders they had seen, as their modern prototypes, and that burgling is not a modern institution. An Arabic tradition ascribes the draining of the lake to Joseph. It is so thoroughly Oriental and interesting that you might like to hear it. It is a translation from an Arabic manuscript once in the possession of Cardinal Mazarin, and contributed by Mr. Cope-Whitehouse to the *Contemporary Review*, September 1887.

Joseph, to whom may Allah show mercy and grant peace, when he was Prime Minister of Egypt and high in favour with Raiyau, his sovereign, after that he was more than a hundred years old, became an object of envy to the favourites of the king and the puissant seigneurs of the Court of Memphis, on account of the great power he wielded and the affection entertained for him by his monarch. They accordingly thus addressed the king. "Great king, Joseph is now very old, his knowledge has diminished; his beauty has faded; his judgment is unsound; his sagacity has failed." The king said, "Set him a task that shall serve as a test." At that time el-Fayoum was called el-Hun, or the Marsh. It served as a waste basin for the waters of Upper Egypt, which flowed in and out unrestrained. The courtiers having taken counsel together what to propose to the king, gave this reply to Pharaoh:—"Lay the royal commands upon Joseph that he shall divert the water of the Nile from el-Hun and drain it, so as to give you a new province and an additional source of revenue." The king assented, and, summoning Joseph to his presence, said, "You know how dearly I love my daughter, and you see that the time has arrived in which I ought to carve out an estate for her out of the crown lands, and give her a separate establishment, of which she would be mistress. I have, however, no territory available for her except the submerged land of el-Hun. It is in many respects favourably situated. It is a convenient distance from my capital. It is surrounded by desert. My daughter will thus be independent and protected." "Quite true, great king," responded Joseph, "when would you wish it done? for accomplished it shall be by the aid of Allah, the all-powerful." "The sooner the better," said the king. Then Allah inspired Joseph with a plan. He directed him to make three canals; one from Upper Egypt, a canal on the east and a canal on the west. Joseph collected workmen and dug the canal of Menhi from Ashmunin to el-Lahun. Then he excavated the canal of el-Fayoum and the eastern canal, with another canal near it called Ben-Hame, to the west. In this way the water was drained from el-Hun; then he set an army of labourers at work. They cut down the tamarisks and bushes which grew there and carried them away. At the season when the Nile begins to rise the marsh had been converted into good cultivable land.

The Nile rose, the water entered the mouth of the Menhi canal, and flowed down the Nile valley to el-Lahun, thence it turned towards el-Fayoum, and entered that canal in such volume that it filled it, and converted the land into a region irrigated by the Nile. King Raiyau thereupon came to see his new province with the courtiers who had advised him to set Joseph this task. When they saw the result they greatly marvelled at the skill and inventive genius of Joseph, and exclaimed, "We do not know which most to admire, the draining of the marsh and the destruction of the noxious plants, or the conversion of its surface into fertile and well-watered fields." Then the king said to Joseph, "How long did it take you to bring this district into this excellent state in which I find it?" "Seventy days," said Joseph. Then Pharaoh turned to his courtiers and said, "Apparently it could not have been done in a thousand days."

Thus the name was changed from el-Hun, or the Marsh, to el-Fayoum, or the land of a thousand days. The last sentence is a pun on the name el-Fayoum; a thousand days is "elf vom" in Arabic, and the true derivation is the Coptic "el phiûm," the sea or lake.

The deepest part of the Wady-Raian depression is 131 feet below the sea level and 61 feet below the Nile; as a reservoir to supplement low Nile, it is calculated to be capable of retaining 2,000 million cubic metres, which is sufficient for the additional requirements for Lower Egypt only. The connecting canal between it and the Nile would have to cross the Bohr Yusuf; its probable cost is stated to be 2,700,000*l.*, and the annual cost of distribution from it 2,800,000*l.* It has not been recommended by the commission, on account of its costliness as compared with other schemes. As regards Lower Egypt it has the advantage of being near its work, and by keeping up the summer level in this district will admit of water being drawn off in Middle Egypt, which must now be allowed to pass down for use in Lower Egypt. The slopes of the Wady are virgin soil, so that there can be no sanitary objection to a reservoir there. From the archaeologists' point of view, it has the advantage of not destroying any ancient buildings.

The highest of the other three sites is at Kalabshi, about forty miles south of Assouan; this was not recommended on account of the great depth of water, which would make a dam at this place unsafe. The height proposed would have been sufficient for Lower and Middle Egypt; its foundation would be on granite. As far as I know at present, the reservoirs at Philæ will not store up more than the same amount. From an engineering point the site is said to be perfect. It is possible that enthusiasm on this account may have caused wider considerations to be lost sight of. A reservoir at Philæ to store sufficient water for Lower and Middle Egypt would tail off near Korosko, a distance of about 100 miles from its dam.

Several other interesting ruins besides Philæ lie within this range. It is expected that some of these will also be submerged. Silselia, about forty miles north of Assouan, is the position of the last of these dams; the river bed here affords a bad foundation of fissured sandstone and bands of clay. The reservoir would have flooded the recently-discovered temple of Kom-Ombos. A reservoir near the Kaibar rapids, a distance of 400 miles above Assouan, would benefit more country than any of the others. Those who know this part of the river well say that the river-bed here would give the best possible foundation for a dam, and that all the other requirements, such as shallow water and ample width, are also present.

Two very serious sanitary objections have been raised to the Philæ reservoir. It is said that the requirements of Lower and Middle Egypt will necessitate the free passage through the sluices of the reservoir of the best water as regards potability, and that when they would be shut down all the Blue Nile water would have passed, and the storage would consist of the unwholesome swamp water of the White Nile, containing the germs of all tropical fevers. The importance of this point will be felt when it is understood that the drinking water of Egypt is solely obtained from the Nile and its canals. Both banks of the Nile south of Assouan are thickly populated, and many villages with their accompanying cemeteries are situated on either side along the whole extent of the proposed reservoir; its waters will wash out these cemeteries and pass over ground that has been fouled by centuries of human occupation. These circumstances constitute the second sanitary objection, and those who have seen the unsavoury surroundings of an Arab village will appreciate its force. The riverside inhabitants of this part number about 30,000 souls who will have to be provided for. It is proposed to meet this difficulty by compensation. Compensation is not easy to obtain anywhere; in Egypt almost impossible. This district is also rich in other ancient remains, some of which may be submerged, and undiscovered ruins may lie buried beneath the soil. There seems great doubt as to the Powers consenting to a loan being raised to construct a reservoir; the temples may therefore yet escape.

CREDITON.

THE ancient town of "Kirtou" was a pleasant rendezvous for a large number of members and friends of the Exeter branch of the Church Defence Institution. The principal object of the excursion was, the *Devon and Exeter Gazette* says, to afford members an opportunity of inspecting the beautiful church of the Holy Cross. The Rev. Prebendary Smith, who has been vicar for more than forty years, kindly consented to describe the church, besides reading a paper on its history and the ecclesiastical connection between Exeter and Crediton. The visitors assembled in the lady chapel. The Rev. Prebendary Smith, after according a welcome to the visitors, said he was proud of the church where he had been so long vicar. He had watched the various improvements made in it with anxiety and interest, and he now felt that it was one of the grandest churches in the county. He was not quite clear, but he took it for granted that it was the ecclesiastical and not the civil history of Crediton they wished to hear about. The civil history of Crediton was very interesting, although unfortunately there were very few means of obtaining information on that head. Of its antiquity there could be no doubt, for they had authentic record of members being sent to Parliament at Carlisle in the thirty-fifth year of the reign of Edward I. Confining himself to the ecclesiastical character of the parish, he remarked that there was no doubt that Crediton was the first see of a Devonshire bishopric, which was established about the year 910. Before that time Wessex formed but one episcopal see, under St. Birinus, at Dorchester in Oxfordshire, which under Bishop Hedda was transferred to Winchester. Upon Hedda's death the diocese of Shireburne (Sherborne), which included Wilts, Berks and the counties of Dorset, Somerset, Devon and Cornwall, was taken from that of Winchester, an arrangement which continued in force for upwards of two centuries, when the Archbishop of Canterbury established the three separate dioceses of Cornwall, Devon and Somerset, and the Bishop of Devon fixed his see at Crediton, where it remained for 140 years. If the Bishop of Exeter should ever require a suffragan bishop he would take his title from Crediton. There were eight bishops of Crediton. Whether they were buried under that church he could not say, but he was much inclined to think that they were. Some years ago, when the outer walls of the north transept were being refaced, he discovered an arch which he was anxious that the governors of the church should have opened. Very probably they would have found a crypt and a number of stone coffins. The last Bishop of Crediton was Leofric, who, at his own request, was transferred to Exeter, and was installed in the year 1050 in the presence of Edward the Confessor and Editha, his queen.

That there was a Saxon settlement of Crediton nearly 200 years before it was chosen as a bishopric there was no doubt. After referring to the birth in the town about the year 680 of Winifrith, afterwards known as Boniface, Archbishop of Mainz and Apostle of Germany, he said it was impossible for them to say what the condition of the church was after Leofric's removal to Exeter. No Saxon remains had ever been found there, although they had been diligently searched for. Whether a body of clergy was left there after his departure could not be known; but there must have been one shortly after, as was testified by the existence of a charter of date prior to the Norman Conquest to the following effect:—"This is the charter of the land which is called Copulstan (the present Coplestone), which the venerable Priest Brithrie gave for the relief of his soul and the souls of his parents to the minister of St. Mary, which is in Crediton, for the maintenance of the canons serving God therein." The church appeared to have had two dedications—one to St. Mary and the other to the Holy Cross. It was doomed to demolition by Henry VIII., but saved from that fate by the zeal of the parishioners, who paid the sum of 200*l*. By a charter dated April 2, 1547, in the first year of the reign of Edward VI., the hereditaments and goods of the church of Crediton, the fabric itself, with all its appurtenances, were vested in twelve governors, who should have perpetual succession. All that ecclesiastical property, and the various privileges and responsibilities connected with it, which were vested in the twelve governors 350 years ago, appertained to their representatives at the present day. The lady chapel was used from the reign of Edward VI. to the year 1860 as a grammar school. In that year the school was built at the head of the town. The lady chapel is now used for week-day services and early celebrations of the Holy Communion. Referring to the architecture of the church, he drew attention to the large windows, remarking that no doubt at one time there was a great deal of stained-glass throughout the church, which would tend to lessen its present light appearance. They had only one stained-glass window now, but they were anxious to get the east window filled in. They had 300*l*. towards it. The cost would be 425*l*., and they found great difficulty in getting the remaining 125*l*. The vicar subsequently pointed out the many interesting features in the church and described their history.

INDIAN ART.

A GENERAL meeting of the Society for the Encouragement and Preservation of Indian Art was held on Monday at the Imperial Institute, under the presidency of Sir James Linton, P.R.I.

The report stated that the financial condition of the Society was not so flourishing as the committee could wish. The expectation stated in the last report that special generous donations would be forthcoming to provide a permanent fund for the heavier expenses of the Society had not been realised. There were two or three notable exceptions to this, for the Maharajah of Jeypore had most generously presented a sum of 100*l*., and two other maharajahs had sent 25*l*. each. These donations enabled the Society to take part in the World's Exhibition at Chicago and other exhibitions during the year, and to place before the public most worthy and beautiful specimens in many branches of Indian handicraft art, which otherwise would never have been seen. The committee hoped that many would be found to come forward and contribute generously in the interests of Indian art, and particularly of Indian artisans, whom the Society earnestly endeavoured to encourage.

Sir James Linton delivered an address, in which he said that, while claiming no great historical or technical knowledge of the industrial arts of India, he could not help having convictions as to the tendencies likely to prove disastrous to the native art of that great country. They had heard and seen a great deal of the endeavour to foster art in India; but the best policy to pursue was that of non-intervention, except for the purpose of preserving absolutely and entirely the national characteristics of Indian art. A friend of his who occupied an important post in India was commissioned to purchase in this country works of art and pictures, which were to be attached to the school of art from which he came. These were pictures of our modern European schools, and they were to be shown as examples worthy to be studied and imitated by the students of that school of art. The pictures purchased were principally landscapes representing places in England and Scotland. Fancy putting things like those before the people of India. Fancy expecting anything from the study of those works but disaster to Indian art. The Society should vigorously protest against such a misapplication of the liberality both of the governing bodies and of the citizens, because no art could flourish or ever be great, no art could by any possibility benefit humanity, that was not absolutely and entirely the result of a nation's individuality—the highest force and the only force that could originate and

carry through to the end a truly great art impulse. It was therefore absurd that we Europeans should insist that what was right for us was right for all, and should try to convert other nations, notwithstanding their racial differences, to our view.

Sir George Birdwood proposed a vote of thanks to Sir James Linton for his address, and also referred to the great debt of gratitude which the Society owed to Mrs. Carmichael, one of the hon. secretaries, to whom the success of the Society is very largely due.

THE PROTECTION OF ANCIENT BUILDINGS.

THE seventeenth annual meeting of the Society for the Protection of Ancient Buildings was held on the 16th inst. at the Old Hall, Clifford's Inn, under the chairmanship of Mr. J. T. Micklethwaite. The place of meeting was well chosen in view of the fast disappearance or remodelling of the old small inns. After the formal business of passing the report, the Chairman referred to the proposed destruction of one of the City churches—St. Ethelburga, Bishopsgate, which is one of the few remaining City churches which dates from before the Great Fire. It has been a good deal knocked about, but as yet has escaped the disgrace of a thorough restoration. A resolution protesting against this threatened destruction was proposed and carried unanimously. The paper of the evening was entitled "Protection and Production," by Mr. Heywood Sumner. By protection, he said, he meant the protection which the Society practised in regard to ancient art, while production is the production of new art. The protection was of two sorts—the preserving of ancient objects *in situ*, and in the second place, where this is not possible, their preservation in museums. This ancient art should be preserved, for it is the record of man. Like creation, it has neither speech nor language, but its voice has gone out into all lands. In addition it is not only beautiful in itself, but it has a power of recreation and inspiration, and from this recreation and inspiration we may learn something of how such work was produced and how such workers are trained, and what was the method of study. And it may be found that the workers were made through the system of apprenticeship, and learned their trade under the restrictions of real work absorbed through practice, and this Mr. Sumner held to be a vastly wiser process than the system of our days.

THE LATE W. CALDER MARSHALL, R.A.

IT is with regret we announce the death of Mr. W. Calder Marshall, R.A., which occurred on Saturday at his residence, 115 Ebury Street, Eaton Square. He was eighty-one years of age, and had been in failing health for some time. Mr. Calder Marshall was a native of Edinburgh. His father was the founder of that well-known firm of Edinburgh goldsmiths, Messrs. Wm. Marshall & Co., the business premises of which in its early days was in the North Bridge. The maternal grandfather of the deceased, after whom he was named, was William Calder, who was Lord Provost of the city in the early years of the century.

Born in 1813, Mr. Calder Marshall (the *Scotsman* says) was educated at the High School and the University. He became a sculptor, an art for which he had shown a decided predilection, and studied under the famous Chantrey and the almost equally well-known Bailey. Still further to forward his professional education, he went to Rome, where at that time the influence of Canova and Thorwaldsen was in the ascendant. By the works of both of these eminent sculptors he was greatly influenced, for although he early broke away from the convention of Canova, and introduced into his work a more naturalistic and modern feeling, he continued to the end a classicist—more moved by the graceful type than by the delineation of individual feeling or character. He practised his profession for some time in Edinburgh, removing to London in 1839, where he early took a good position in the world of art, and retained it until the close of his life.

Mr. Calder Marshall was elected an Associate of the Royal Scottish Academy in 1840, and of the Royal Academy in 1844, and he became a Royal Academician in 1852. He resigned his Associateship of the Scottish Academy when he was elected to the Royal Academy. In 1861, as a recognition of his merits, he was elected to the hon. membership list of the Royal Scottish Academy. Mr. Calder Marshall's sympathies were all on the side of ideal art, and his groups or single figures selected from Greek and Roman mythology, or from ancient history, were always well composed, graceful in form and dexterously executed. *The Broken Pitcher* was completed in 1842 for the Art Union, the subscribers of which frequently did him the honour to select replicas of his works for prizes. His *First Whisper of Love* was the first Art Union prize in 1845; *The Dancing Girl Reposing* obtained the Art Union premium

of 500*l.*, and of it reduced copies in Parian were distributed among the subscribers. His *Sabrina*, a water nymph, was another famous figure—one of the best, some of his friends thought, that he ever did—and it had a wide circulation in the shape of a porcelain statuette. For the Houses of Parliament Mr. Calder Marshall executed the statues of Lord Clarendon and Lord Somers; and from his studio came also not a few statues of public men, erected in London and other English towns. The bronze statue of Sir Robert Peel at Manchester is his, as also the statue to Jenner which formerly stood in Trafalgar Square, and is now re-erected in Kensington Gardens. Among his other works may be mentioned the statues to Crompton, the inventor of the mule spinning machine, in Bolton; to Sir George Grey in Cape Town; and to James, seventh Earl of Derby, for the spot on which that nobleman was executed at Bolton. In the great competition in 1857 for a national monument to the Duke of Wellington, in which artists from many countries competed, Mr. Calder Marshall had the distinction of receiving the first prize of 700*l.* But while this was so, the monument was actually erected from other designs, though Mr. Calder Marshall executed some of the bas-reliefs in the side-chapel in which the memorial was placed. He was chosen to execute the large group symbolical of *Agriculture* at the base of the Albert Memorial in Hyde Park, and another honour conferred on him was his appointment as a member of the Royal Commission to represent British and Colonial exhibitors at the International Exhibition held at Paris in 1878. In recognition of his services then he was made a Chevalier of the Legion of Honour.

One of the best busts Mr. Calder Marshall ever executed was that to the poet Rogers, of whom he was a friend. Though he was a frequent exhibitor at the Royal Scottish Academy, we are not aware that he ever received a commission to execute any public statue north of the Tweed. He, however, in 1854, presented a grand example of classical sculpture to the Royal Scottish Academy, called *Ajax Praying for Light*. This colossal figure, which stood for many years in the vestibule of the Academy, is now in the Museum of Science and Art, Chambers Street, on a loan from the Academy.

A few years ago, when failing health prevented further work being done, Mr. Calder Marshall went upon the retired list of the Royal Academy, and about the same time he, with great public spirit, distributed the casts of his chief works among several of the museums of the country. A number went to the Crystal Palace, others to Manchester, and others to the Museum of Science and Art, Edinburgh, where some of them constitute a prominent adornment of the outer hall. Among others there which may be mentioned are his *Eve*—a nude female figure seated on a bank looking at the serpent on the ground beside her; *Deborah* (1842)—the Jewish heroine singing her immortal song of victory; *David*, an admirable semi-nude figure of a youth leaning on the sword of the giant whose head lies at his feet; and a thoughtful statue of Chaucer, the father of English poetry, arrayed in a long robe, and having pencil and book in his hand. Inside the Museum is the *Ajax* already referred to—a grandly-modelled figure of a warrior; a spirited group, called *The Young Briton*—the early British mother teaching her boy endurance being of a gracious type—and the *Prehistoric Artist* carving with an iron tool a mammoth's tusk. These works are very representative of the trend of the art of Mr. Calder Marshall, and of the ability which he put into the execution of all that he did.

As a man Mr. Calder Marshall was of a quiet and reticent demeanour, but he was widely respected by a large circle of friends, not less for his artistic qualities than for his upright life. Mr. Calder Marshall was a lifelong friend of the late Allan Fraser, and he was a trustee under his will in connection with the scheme for promoting the education of Scottish artists, which, however, has not yet taken shape. The deceased is survived by a daughter and two sons, one of whom, Mr. Charles J. Marshall, is an architect in London. Three of Mr. Calder Marshall's younger brothers are well-known Edinburgh citizens.

THE CHAPEL ROYAL, HAMPTON COURT.

THE Chapel Royal at Hampton Court is about to be closed for a period of three or four months, while some extensive alterations are carried out. The alterations consist chiefly in the removal of sixteen windows, and their restoration in the style in which they were originally. The windows are now very plain, and filled in with ordinary glass. A short time ago an old window, which had been blocked up and concealed for a great number of years, was discovered over the altar in its original state. In the time of Henry VIII. the windows were filled in with stained and ornamental glass, but this was all destroyed by the Puritans in 1645, orders being given that they should be "newly glazed with plain glass." This was done, and since that time no attempt has been made to revert to the original style. It is intended to restore the mullions and tracery, and insert tinted glass. Six of the sixteen windows

are to be similar to those in the great hall, and will contain the heraldic badges of Henry VIII.—the Lion, the Portcullis, the Fleur-de-lys, the Tudor Rose, the Red Dragon of the House of York, and the White Greyhound of the House of Lancaster—with mottoes running obliquely across. The chapel will be used for the last time before the alterations on Sunday next, and while it is closed the services will be held in the great hall.

THE ROYAL ACADEMY AND LITHOGRAPHY.

THE following letter from Mr. George Thomson appeared a few days ago in the *Times* :—

If I may claim the hospitality of your columns, there is a matter touching a recent decision of the Royal Academy and its treatment of artists which, insignificant enough in itself, is of such importance in principle as deserves, I think, some public notice. I refer to, and here protest against, a proposition which the President and Council appear to have made to themselves—that examples of the art of lithography shall be deemed inadmissible to their exhibitions. This reactionary decision is the more to be deplored, as it constitutes a reversal of the larger policy which formerly prevailed. For lithographs were at one time frequent in the Royal Academy, as may be seen by any one who searches catalogues of the "fifties" and the "sixties" under the names of Lynch, Vinter, Maguire, Lane and others. I do not know when the new policy was initiated, but I may say that a lithograph has appeared in the Academy so recently as 1892. This was a reproduction by Mr. Thomas Way from Mr. Whistler's portrait of his mother, and some of your readers may remember the work. The print, it is true, was not described as a lithograph, and it is possible that it was hung in academic ignorance.

This matter is of special interest at the present moment, when effort is being made by a number of painters to revive this beautiful art as a mode of original artistic expression. The lithographic stone presents facilities for conveying some artistic qualities much valued at the present time. The most autographic of drawing and printing processes, with qualities and limitations peculiarly its own, its possibilities have been little more than suggested in this country. While claiming no superiority, I admit of no inferiority in capable hands to either plate or wood-block printing.

My second complaint, of smaller general interest perhaps, is of the incivility, as it appears to me, of the Academy in this, that having refused my work—a lithograph—upon a rule not hitherto known or published, so far as I can ascertain, it has completely ignored repeated application for an explanation. And this, sir, though of little moment to the majority of your readers, should be of some concern to the general body of artists, on whose co-operation the success of the Academy so largely depends.

The circumstance which is the occasion of my complaint may be gathered from the following particulars and correspondence. It happened that I submitted to the selecting committee of the present exhibition a lithograph—a slight thing in itself—drawn, printed and entirely executed by myself. Some three weeks afterwards I received the communication given below, and thereafter addressed to the secretary the inquiries which follow :—

"Royal Academy of Arts :

"(Post-mark 23) April, 1894.

"Sir,—I am desired by the President and Council to inform you that the work sent in by you for exhibition, being a lithograph, is inadmissible, and to request you to remove it as soon as possible.

"Your obedient servant,

"G. Thomson, Esq.

"FRED. A. EATON, Sec."

"Strand-on-the-Green, Chiswick, W. :

"April 24, 1894.

"Sir,—I am in receipt of your communication with reference to a work which I submitted to the selecting committee for exhibition at the Royal Academy. In this letter I am informed that, 'being a lithograph,' my work is inadmissible.

"I have searched the instructions issued to intending exhibitors, and find no reference whatever pointing to lithography as a means of artistic expression which is excluded from the exhibitions of the Royal Academy. I am therefore at a loss as to the meaning of your communication; and as this decision of the President and Council, so far as I know, is quite unprecedented, I think that I am entitled to an explanation. I should be greatly obliged if you would inform me upon what grounds or under what rule drawings printed by this particular means are inadmissible at the Royal Academy.

"I am, Sir, yours very truly,

"GEORGE THOMSON.

"Fred. A. Eaton, Esq., Secretary to the Royal Academy."

"Strand-on-the-Green, Chiswick, W. : May 10, 1894.

"Sir,—I wrote a letter to you about two weeks ago, in which I asked to be informed under what rule a lithograph submitted by me had been adjudged an inadmissible work. I

have had no reply to my question, and I now write to ask if I am to be favoured with an answer.

"I am, Sir, yours very truly,

"GEORGE THOMSON.

"Fred. A. Eaton, Esq., Secretary to the Royal Academy."

Neither of these letters has been answered, though six weeks have now elapsed. And certainly it is not for me to open further communication.

I do not pretend that the revival of lithography will suffer mortal hurt for being snubbed by the President and Council of the Royal Academy. Other forms and phases of art have similarly suffered, to find their refuges elsewhere, and even now the art of lithography receives due encouragement upon the other side of Piccadilly. But is it too much to ask that the Academy should plainly publish all its rules and treat intending exhibitors with common courtesy?

There is a minor circumstance worthy, perhaps, of mention, which enriches the ludicrous element in this affair. There is marked upon the back of the frame by the Academy official the word "inadmissible," and partly obliterated, the letter "D." This letter in academic significance implies that the work had been provisionally accepted for exhibition; that, provided space were found, it would have been included in the exhibition. The "D" or "doubtful" class forms the bulk of an Academy show in the proportion, it is said, of nine out of ten exhibited works. An offending picture, therefore, can clearly carry its condemnation, not upon its face, but on its back—in the written description of the author. It may be good to the academic mind in itself, but bad because it is a lithograph.

NILE RESERVOIR AND TEMPLE OF PHILÆ.

IN a letter to the editor of the *Times*, Mr. R. Hamilton Lang writes:—Permit me very briefly to suggest that there is one point in the case "Nile Reservoir *v.* Temple of Philæ" which is not satisfactorily proven by anything yet published on the subject.

I am ready to admit that the storage of a certain quantity of water by means of a reservoir is necessary for the progress of the material interests of Egypt, and I accept without hesitation the opinion of Sir Benjamin Baker that the Assouan reservoir is best adapted to store with safety the enormous volume of water for which Mr. Willcocks provides, but nothing which I have yet read has convinced me that the reasonable requirements of Egypt necessitate the construction of a reservoir of the dimensions proposed.

The importance of this point need not be dwelt upon. It is evident that, although a reservoir carrying 22 mètres head of water may submerge the Temple of Philæ, one of 12 or 15 mètres head of water may not do so. And if it can be proved that a reservoir of the smaller dimensions will amply suffice for all the probable wants of Egypt during the next 15 or 20 years, then I venture to submit that it would be unjustifiable to destroy the Temple of Philæ.

Sir Benjamin Baker tells us in his article in the *Nineteenth Century* for May that the proposed reservoir will increase the supply of water at low flood by an amount considerably larger than the supply which is now available. In other words, the reservoir in its projected dimensions will provide for a summer culture more than double of what now exists in Egypt. Roughly speaking, the present summer culture of Egypt may be put down at 1,400,000 acres. The projected reservoir provides for that area being raised to 3,000,000 acres. I make bold to say that twenty years hence Egypt will not have increased that area to 2,100,000 acres, and if she attains this latter figure she will have made marvellous progress.

It would make this letter too long to explain fully all the reasons which lead me to make the assertion that an increase of 50 or 60 per cent. in the present supply of water for summer culture is largely sufficient for the requirements of Egypt during the next twenty years, but if the question is to be seriously examined I am ready to give them.

Meantime I think it is fair to ask Sir Benjamin Baker kindly to inform us what are the dimensions of a reservoir at Assouan which would not submerge the Temple of Philæ. Enlightened upon this point, it would be reasonable to consider whether the volume of water thus secured is not a sufficient present boon to give to Egypt. The opinion of Sir Benjamin Baker on another point would also be grateful, viz. given the volume of water to be half of what Mr. Willcock's scheme proposes, would a reservoir at Silsileh instead of Assouan not be feasible?

Fifteen or twenty years hence the facilities of Egypt for storing water may be much greater than they are to-day, for the reoccupation of the Soudan may afford sites for storage superior to those now available. Personally I also attach considerable importance to the suggestion of Mr. Garstin, that possibly it may be found that the natural depressions known to exist at various points on the course of the Nile may be utilised for the storage of water at a comparatively small cost. Further,

Upper Egypt or perhaps the southern half of it might receive its supply from a canal similar to the Ibrahimieh Canal in Middle Egypt and drawing its supply above the action of the reservoir, and this would be especially easy were the reservoir situated at Silsileh. In fact, there are so many possible ways of increasing, whenever it is desired, the water supply that no risk is run in limiting the reservoir now projected to the probable requirements of Egypt during the next twenty years, and if by such a limitation the Temple of Philæ could be saved all lovers of that beautiful monument of the past would be grateful.

WORKHOUSE SCHOOLS.

AT the last meeting of the Chorlton Board of Guardians a report of a sub-committee of the house visiting committee, appointed on January 10, in reference to the removal of the school children from the vicinity of the workhouse was adopted. It stated the subject of the removal of the children from the proximity of the workhouse has at various times received the consideration of the guardians, and although it has on every occasion been thought most desirable, difficulties have arisen which have hitherto prevented the attainment of this desirable object. The present time, however, seems opportune for carrying out this needful scheme, as, unless the children are removed, further provision will have to be made for giving additional accommodation, both to the body of the house and also to the lunatic wards. The following resolution was adopted on January 10, when the sub-committee was appointed:—"That, with the object of providing additional workhouse accommodation, the children at present in the workhouse schools be removed into the country and cottage homes provided for them, and that the present school buildings be utilised as lunatic wards and the present lunatic wards be added to the body of the house." The first thing to be considered was as to the system; whether it should be cottage homes such as exist at Leicester, Birmingham, Swansea and other places, or cottage homes as recently introduced by the Sheffield Guardians. "Sheffield was accordingly visited, the arrangements and details of the homes examined, and, though we felt there was much to admire in the innovation, yet we could see that unless the scheme could be worked, and worked always, under the most favourable conditions possible, it was open to very grave objection, and we were reluctantly forced to the conclusion that we could not recommend its adoption to you. For the number of children always likely to be chargeable to this union there would appear to your sub-committee no better plan for dealing with them than in cottage homes such as are found at the places mentioned. This being the case, the site of the proposed homes was our next consideration. Advertisements were inserted in all the local and neighbouring papers and applications made to almost the whole of the estate agents in the vicinity, inviting offers for sufficient land for the erection of such homes, in answer to which some fifty plots were submitted to us, and after inspection and careful examination we are now prepared to recommend less than half a dozen to you for selection. And so that we might be in a position to recommend to you the most modern of recent erections we consulted the Local Government Board, who expressed the opinion that the Leicester, Birmingham and Swansea schools were the best. Several members of the sub-committee visited these places. In conclusion we recommend (1) that the sites selected by your sub-committee be visited by the whole Board; (2) that in our opinion the Leicester Cottage Homes are best adapted to serve as a model where new schools are required by a union similar to Chorlton, but with a less expensive style of architecture."

ST. MICHAEL'S CHURCH, LINLITHGOW.

A PARTY of members of the Glasgow Ecclesiological Society recently visited the church of St. Michael, Linlithgow, at present in process of restoration under the direction of Mr. John Honeyman. Mr. Honeyman being unavoidably absent sent the following notes, which were read after the members reached the church, viz.:—"Mr. Honeyman had suggested a visit to St. Michael's Church that they might get some idea of the great beauty and importance of the building. He hoped that on some future occasion, when the operations now in progress were further advanced, they would revisit the church and devote a day to its examination. Meantime he had no doubt that even a passing look into it would greatly interest them and induce them to help on the work if it should be in their power to do so. Fortunately the fabric was in a good state of preservation generally, but when the parish church was transferred to the east end, nearly a hundred years ago, an immense amount of damage had been done in a most reckless manner, and to repair that damage required more funds than the committee had been able to raise in the locality, but he had no doubt the amount required would be forthcoming if the national importance of the work was fairly brought before

wealthy Scotsmen throughout the country, and he would venture to say throughout the world. When the partition wall was erected at the west side of the transept the chancel arch had been deliberately taken away and the responds cleared off, so as to allow one or two more people in the end gallery to see the minister, and the piers of the chancel were seriously injured by the rests for the gallery beams being cut right through the pier. The repair of these piers is the chief structural difficulty, but the holes in the responds and in the walls are easily managed, and are already partly restored. They would observe that the floor of the nave had been raised to the same level as that of the chancel. They proposed restoring it to its original level, which would cost a good deal, but he was sure they would agree with him in thinking it a most proper change. Then they would notice that while the aisles have stone vaulting of very simple and elegant design, the nave and chancel have sham vaulting of stucco. This was abominable in every way and seriously affected the proportions of the building. There would be no difficulty in dealing with it effectively if only they had plenty of money, but failing this, he was almost inclined to think that it would be advisable to sweep the whole away and expose the rough king-post roof which is above it. The nave was never designed to have anything but a wooden roof. The piers are slender and the span is wide—wider than Glasgow or even St. Andrew's. The building was exceedingly valuable as an example of Scottish architecture of the fifteenth century. It was a harmonious and graceful design, and he thought by far the finest church of the period now remaining in Scotland." A hope was expressed by those present that liberal contributions would be forthcoming, so that the minister of the parish and the architect would not be hampered in their efforts to restore this ancient and historic sanctuary to something like its former beauty and splendour.

THE TRON STEEPLE, GLASGOW.

IN few cities of Great Britain, says the *Glasgow Herald*, is the past less conspicuous in the present than Glasgow. Although, to those who know their native city well, there are in almost every street east of Buchanan Street houses which have their history—and some of them have strange histories—yet there are not many which architecturally have any claim to notice. The old city of Glasgow was a very small place, and long ago consisted of little more than one straggling street, running from the cathedral to the Clyde, with branches westward. As every one knows, the Bishop's Castle stood where the present infirmary stands, and in the neighbourhood were the houses of the various canons of the cathedral. There were gardens around those houses, and the Molendar, then a clear stream, flowed down to the equally clear and fish-thronged Clyde. The town was for many a day celebrated above all for the clearness and salubrity of its atmosphere. Of the buildings which formed the little episcopal city few traces remain—in the first place because great fires from time to time ravaged it, and in the second place because, when the influence of trade began to work, the old buildings were rapidly modernised. Even Hamburg, which is supposed to be the least romantic of all Continental cities, far outvies in picturesqueness anything that Glasgow can show. Still the city has none of the wearisome monotony which characterises the plan of American towns, and there still remain some reminders of former days in the three towers which in somewhat unexpected places show themselves amidst the bustle of the working-day world. Of the three none is better known to Scotsmen than that of the Tron Church, which has at present secured the doubtful honour of being the subject of a vote in the Town Council.

In olden times near the west port of the city there was a tract of ground associated from remote antiquity with St. Thenaw, the mother of St. Kentigern, and the approach near to it was known as St. Thenaw's gate. There was, we think, a small chapel there, and there was certainly a St. Thenaw's burn, one of the numerous rivulets which then crossed the fields west of the Cross, now covered by Tron Gate, Argyll Street, and the western portion of the city. It is scarcely necessary to remind readers that the name of St. Thenaw became corrupted into the present form of St. Enoch—a saint unknown to any calendar. In 1525 Gavin Dunbar, Archbishop of Glasgow, gave his consent to Master James Houston, vicar of Eastwood, founding a church "to the Lady Virgin Mary of Loretto and St. Ann her mother" on the south side of St. Thenaw's gate; and by the courtesy of Mr. Renwick, of the town clerk's office, the present writer has been permitted to examine the original document, which still bears in excellent preservation the archiepiscopal seal.

The archbishop had only been eight months in his office when this deed was executed, for he succeeded Archbishop Beaton upon the translation of the latter to St. Andrews, and came fresh to Glasgow from his office as tutor to King James V. The provost and bailies were not slow to encourage the pious

ardour of James Houston, the founder of the new church, and in 1529 they granted a charter giving, in honour of the Virgin Mary and her mother, and to the said Master James Houston, and to the eight chaplains of the church, sixteen acres of land on the east side of Glasgow, commonly called the Gallowmuir, of which sixteen acres eight lay on the south side of the muir between the lands of Barrowfield on the south and the common muir on the west, and the remaining eight acres upon the north side of the muir, adjacent to the lands of the Sub-dean of Glasgow, commonly called the Wester Craigs, and the town's muir on the west and south portions and the lands of the treasurer of Glasgow on the east parts, to be holden of the town in free gift for prayers, &c. This charter was confirmed by Archbishop Dunbar ten days after its execution by the provost. In subsequent years the lands were reconveyed to the city. Ten years after the archbishop's confirmation Master James Houston, now described as "Sub-dean of Glasgow, founder of the Collegiate Church of Saint Mary the Virgin and Saint Ann her mother, otherwise called Our Lady College," executed a deed whereby he appointed the Lord Rector of the university and the Dean of the Faculty of Arts visitors of the collegiate church aforesaid, and bequeathed certain yearly sums to be paid to them for making such visitations. According to most of the local histories, the church itself was not built until 1540, but we are inclined to think that this must be erroneous in view of the above documents. It is also clear that when reference is made (as in some cases) to the dedication of the church to "Saint Mary and Saint Michael," there must surely be some error. At all events, the church soon lost its name, and from the fact that the Tron, or weighing machine by which were weighed the goods of the persons coming into the city, was situated at the gate adjoining, it became known by the name the present church still bears, viz., that of the Tron Church. The church was but a new building when Cardinal Beaton, the city's former archbishop, was murdered in St. Andrews, and although the years between his death (1546) and 1553 were the breathing time of the Church, the ecclesiastical decay had already spread far. It is a fact which cannot be too often insisted upon that the ruin of pre-Reformation ecclesiastical edifices was due rather to the indirect than the direct action of the reformers. The number of churches which were wrecked is small, but the number of churches which were allowed to fall into decay, owing to the alienation of the revenues by which they were supported, is considerable. It would be out of place here to refer in detail to the curious and indefensible alienations of ecclesiastical property, which were not less numerous in the West of Scotland than elsewhere. But the fact itself should be borne in mind. The Reformation in Scotland is generally stated to have taken place in 1560, although there is considerable room for doubt whether the Protestant ascendancy was completely established for a considerable period afterwards, except in districts where the reformers were in a decided majority. The churches in Glasgow seem to have suffered like the churches elsewhere from the want of funds to keep them in repair, and in 1568 we find the kirk-session ordering the master of the college to repair the Blackfriars Kirk, a repair which must have been limited to the fabric of the edifice, because, the church having been already swept of pre-Reformation altars, there could be little or no furniture in it. Even in the cathedral, as appears from an order of the kirk-session in 1589, there were only forms for the men, the women being enjoined to bring stools with them if they required seats. In 1592 the ruined state of the Tron Church attracted public attention, and it was ordered to be repaired for public worship. Its first minister was John Bell. The present steeple was built in 1637; and it is therefore about ten years younger than its neighbour, the Tolbooth steeple, at the north-western corner of the High Street and Tron Gate.

The Tron Gate Tower was just a year old when the most notable event which ever took place in Glasgow, the meeting of the General Assembly in the cathedral, brought together a most remarkable crowd of peers, magistrates, barons, burgesses and ministers. Scarcely a notable man in Scotland was absent from the General Assembly of 1638, and a special gallery was set apart for young noblemen who were not members of the house. This was the famous assembly which, undeterred by the withdrawal of the Lord High Commissioner, proceeded to the trial of the Scottish bishops, and deposed them all, not merely from their bishoprics, but from the office of the ministry; while, in addition, it excommunicated eight of them. It sat from November 21 to December 20. Then, as now, the provost (not yet a lord provost) was a Mr. Bell. The provost was not unaware of the delicacy of the proceedings within the High Kirk, and frequently placed the position of matters before his colleagues and craved their advice. On November 29 he desired to know whether, the Lord High Commissioner having withdrawn, the Assembly should continue to sit, and the Town Council instructed him to vote that the Assembly should proceed with its business. A week later he asked for instructions on such comprehensive subjects as the deposition of the bishops;

the abjuration of episcopacy, the abrogation of the previous Assemblies, and sundry other little matters, and by a majority the Council instructed him to vote for all such things.

The old Tron Church, which had begun its existence as a collegiate and Catholic foundation, survived until 1793, when it came to an untimely and entirely unexpected end. The session-house had long been in use as a meeting-place of the presbytery of Glasgow, but the economical citizens having determined that it should be contrived a double debt to pay, the ministers of the morning were replaced in the evening by the city guard, a body at that time of more or less amateur police or vigilance committee, who took duty by rotation. It appears that the watch left the session-house at three o'clock in the morning of February 15, 1793, by which time it was probably anticipated that even the exuberant spirits of Glasgow youth would have had time to cool down. They were, however, greatly mistaken. As it happened, the members of a society of disciples of Tom Payne, who were designated the Hell Fire Club, were on their way home when they observed the cheerful blaze of the guard-house fire, and made their way into the session-house. According to Dr. Mathie Hamilton, "while warming themselves at the fire and indulging in jokes against one another as to their individual capacity to resist heat, with reference to an anticipated residence in the headquarters of the club, they placed what inflammable matter there was at hand on the fire to increase it, and ultimately having, in bravado, wrenched off and placed some of the timber of the session-house on the ignited mass, they could no longer endure the heat, and fled in dismay from the house, which contained much dry wood, as it was seated like a church. It was soon a mass of fire, and the flames caught the church, which was totally destroyed in a terrific conflagration, so that on the north side of the Trongate, between it and Bell Street, where Antigua Place in Nelson Street now is, a quantity of hay in stack was with difficulty saved from the embers which were wafted through the air from the blazing church. The steeple, however, escaped all damage." In 1794 James Adam, the architect of Glasgow Infirmary, was instructed to prepare plans for the erection of a new church, which is now almost for the first time exposed to the citizens' view by the destruction of the tenements which formerly obscured its somewhat unsightly appearance.

It has been mentioned above that the Collegiate Church of Our Lady and St. Ann had early acquired the name of the Tron Church from the proximity of the weighing machine. Latterly the tron itself was located in the street chamber of the tower, until the progress of time having rendered the arrangement antiquated, the chamber was arched and a free pathway provided along the pavement of the busy thoroughway on which the tower stands.

During its long watch of over two centuries and a half, the Tron Steeple has seen many a change pass over Glasgow. Built when the little city was only beginning to emerge from the Mediæval Ages, which lingered longer in Scotland than in England, under its shadow have passed all the generations of citizens who have built up the commercial fame of Glasgow. It has seen the tobacco lords of Virginia majestically tread the "plane stanes" in their scarlet cloaks, and their more sombrely-clad successors, busied in other pursuits which have brought wealth and honour to St. Mungo's city. Formerly it stood in the very midst of the social life of the citizens, for there were few of the many social clubs for which Glasgow was famous that did not meet in the inns of the neighbourhood. Now it stands, a record of former days, adding picturesque antiquity to a street which otherwise is entirely modernised. Such projecting towers add much to the fame of the streets of Nürnberg and Ratisbon, but on the Continent they were in most cases built as defensive adjuncts to the dwellings of the local barons who dominated the burghers. In Glasgow no such gloomy associations cling to the tower, the demolition of which is so lightly proposed, and it is to be hoped that nothing will be hastily agreed to which will deprive the city of a time-honoured landmark.

THE HELLENIC SOCIETY.

THE annual meeting of the Society for the Promotion of Hellenic Studies was held on Monday. Professor Jebb, M.P., who presided, in moving the adoption of the Council's report, gave a short account of the more important discoveries that have been made in Greek archæology during the past year. The French archæologists at Delphi have found, among other things, the treasure-house of the Athenians (which was built soon after the battle of Marathon), and marble slabs containing the now famous hymn to the Delphian Apollo. Of this there are fourteen fragments in all, the principal one containing some eighteen lines. The musical notes are denoted by letters which are sometimes tilted or turned upside down in order to supply more symbols. The clue to the interpretation of these is found in a Greek writer named Alypus, who dis-

tinguishes two systems of notation, one for voices and the other for instruments—presumably the lyre and flute. There are specimens of both systems among the Delphian fragments. The date of the hymn is thought to be the third century B.C., and it is the most authentic and extended piece of Greek music as yet known. The British School at Athens have been investigating the course of the aqueduct in connection with the spring Callirhoe. In Cyprus the trustees of the British Museum have undertaken the excavation of the necropolis of Amathus, while German explorers have been working in the plain of Troy. Professor Armitage Robinson has been searching for Greek manuscripts in Constantinople. In the library of St. Sofia he found none, but in another library he discovered about forty, which, however, do not seem to be very valuable. Mr. Ernest Gardner, in seconding the report, gave some particulars about the damage caused to antiquities in Greece by the recent earthquakes. The Parthenon seems to have suffered considerably. In the ballot for members of the Council for the ensuing year the official candidates were elected unanimously, and the proceedings closed with a vote of thanks to the Chairman.

GENERAL.

Professor Banister Fletcher has declined to contest Rochester at the next Parliamentary election, on the ground that his work will prevent his giving the necessary time.

Lord Waterpark has refused an offer of 95,000*l.* for his Derbyshire seat, Doveridge Hall, which has been for some time in the market.

Eleven Pictures recently presented to the Dudley Art Gallery have been placed among the permanent collection. *Market Girls*, a Brittany study, by H. H. Robinson, exhibited in the Academy in 1886, was purchased for the gallery by Messrs. C. H. Palethorpe and A. G. Hooper. The other pictures—ten in number—form a legacy by the late Mr. Richard Hopkins, of Emscote.

The Art Collection at Guildhall will close on Sunday, July 1. Nearly two hundred and fifty thousand persons have up to now visited it, and the gallery continues to be thronged daily. It is acknowledged to be the best collection which the Corporation has yet been able to gather together.

An Anonymous Donor has contributed 2,000*l.* for the cost of one house at the Royal National Hospital for Consumption, Ventnor, in memory of two daughters who died from consumption.

A Memorial of Barye, the French sculptor, consisting of a medallion portrait with representations of some of his works, was unveiled on the Ile St. Louis, Paris, on Monday.

A Design by Mr. J. A. Eggar has been adopted for the school in East Street, which is to be erected by the Farnham School Board. Premiums were awarded to Mr. Paxton Watson and Mr. A. J. Nash.

An Exhibition of ecclesiastical and educational art will be held in Exeter during the Church Congress, from October 8 to October 12.

The Photographic Salon will be opened for the second time in the Dudley Gallery on October 1, and will not be closed for a month. The exhibition will be confined to "pictorial photography in which there is distinct evidence of personal artistic feeling and execution."

The Estate of the late Colonel William Haywood, engineer to the Commissioners of Sewers, has been sworn at 42,606*l.* gross value and 29,957*l.* net value.

Mr. Leader Williams, the engineer of the Manchester Ship Canal, has received a letter from Lord Rosebery intimating that he is to be knighted in recognition of his engineering services.

Tablets, with portraits of Leopold Ernest, who was architect in charge of St. Stephen's, Vienna, from 1852 until 1862, and of Friedrich Schmidt, who held the same office from 1863 until 1891, have been set up on each of the south portals of the church.

Mr. William Hart, the American landscapist, died in New York on Sunday, in his seventy-first year. He was born in Paisley, but has lived in the United States since 1831.

Mr. Delissa Joseph is the architect for the schools and minister's house in connection with the Hammersmith and West Kensington Synagogue, the foundation-stones of which were laid last Sunday by Mr. B. L. Cohen, M.P., when the Chief Rabbi officiated.

The Marquis of Lothian on Wednesday evening presided at the annual dinner of the Artists' Benevolent Fund.

The Death is announced of Mr. Andrew Maitland, the senior partner of A. Maitland & Sons, architects, Tain, in his ninety-second year. For the last half-century he was a prominent figure in Ross-shire.

The Architect.

THE WEEK.

THE meeting of the Institute of Architects on Monday was characterised by something rather exceptional, as the chief interest centred on two such eminent men as Mr. F. C. PENROSE, the newly-elected President of the Institute, and Sir FREDERIC LEIGHTON, the President of the Royal Academy. That so accomplished an artist should receive Her Majesty's gold medal from the hands of such a veteran in art as Mr. PENROSE was a circumstance none the less pleasing because it was fortuitous. However proud we are of Mr. PENROSE as an ornament to the profession which he has so worthily and assiduously served, the estimation in which he is held abroad scarcely is second to our own appreciation. Sir FREDERIC LEIGHTON, in returning thanks for the honour conferred on him, acknowledged the claims that architecture had on the gratitude of mankind. He was induced to enter on a somewhat treacherous ground of discussion as to the relations of architecture with the other arts. He, if we interpret his meaning aright, drew a comparison between the relations that existed between them in Mediæval times unfavourable to the customs of the present day. Some men now seemed, he said, to have assumed that the only function of the graphic arts was to ornament architecture. The old masters, however, had never been prepared to strike or veil their colours, nor did he believe in any "gilded vassalage of the other arts to architecture." Architecture, from his point of view, consisted in a building that showed fitness for its purpose, and, in addition, was lighted up by appropriate beauty—not beauty thrown over it like an adventitious garment or meretricious gauze—but the beauty of the soul of the building looking out of it. A sharpened sense of beauty, he considered, was the true hall-mark of every artist, whether painter, architect or sculptor. That the three arts might gain indefinite enhancement by more close spiritual communion he did not doubt, though the gain to architecture depended on a more subtle and sober use of ornament.

THE judgment which was given in the Queen's Bench Division on Monday does not determine the question whether any of the London authorities can take part of a house for the purpose of widening a street without paying the value of the whole of the building. That important point will have to be fought out at a trial. All the judges could do was to say there was no reason to interfere with the action of the Kensington Vestry when they sought to have compensation assessed for the value of a portico, step and cellar flap which were required for widening a footpath. The question whether partial compensation is adequate has not been determined in respect of London, although MICHAEL ANGELO TAYLOR'S Act, which authorises the compulsory taking of "any houses, walls, buildings, lands, tenements and hereditaments, or any part thereof" for street improvements has been in force for more than a century. The owners of the property sought to restrain the vestry from summoning a jury or from taking other proceedings which would relate only to the portion of the property which was immediately needed. Mr. Justice CAVE admitted that there were no decisions on the point, but as land could be taken or a part of a garden in front of a house, it might be considered that the removal of a part of a house could be enforced so long as the house was left substantially in its former state. The removal of a portico might make it necessary to alter the rest of the house structurally, and to adapt it to new purposes, or to leave it suitable only for a different kind of business or business of a more limited nature, and in such cases it would not be within the powers of the vestry to force the owners to give up the portion. But if the business could be continued as before, and the alteration did not interfere substantially with the business, then the vestry could take it. But the effect of the removal could only be determined at the trial of the action, when all the circumstances would be considered. Mr. Justice

COLLINS took a similar view. He said a house is *primâ facie* a unit incapable of being divided, but there are cases where certain portions can be cut off without destroying the identity of the house as a house. There is nothing in such a case to prevent the compulsory powers of the vestry from being exercised, but if what is sought to be removed is so indissolubly linked to the house that it cannot be removed without destroying the identity of the house, then the whole must be dealt with. It remains, therefore, for the plaintiffs and their advisers to consider how far it can be proved that the portico, step and cellar flap will affect the value of the premises, which is a subject for expert evidence. A portico is often an important feature in an hotel or public-house. Business could be conducted after its removal; but, as the appearance of the house would be changed, it might be that the business would be of a more limited nature. The decision of the two judges has narrowed what is at issue, so that the action becomes one of compensation.

THE architectural works which have been sent from Rome by holders of the Prix de Rome, and are seen in the Ecole des Beaux-Arts, are of the usual quality. M. SORTAIS shows a restoration of the Temple of Canopus, one of the adjuncts of Adrian's Villa at Tivoli, in which religious exercises of a sensuous character were carried on. Another shows the white Parian marble arch of Trajan in Ancona, which some consider to be finest of all the triumphal arches, although it no longer possesses the ornamentation and sculpture with which it was enriched, and a third the tomb of GATAMELATA, in Padua. M. SORTAIS' contribution is the most important. M. PONTREMOLE sends a drawing of the *Lion of Florence*, and M. EUSTACHE a drawing of the tomb of the Doge VENDRAMINI, in Venice, one of the noblest examples of its class, which is supposed to be wholly or partially the work of ALESSANDRO LEOPARDI. M. BERTONE is represented by a study after the antique.

WE have been asked to mention that some of the statements about private galleries in Paris, which we printed a fortnight ago on the authority of the *Figaro*, have not the exactitude which is the characteristic of the *Architect*. MEISSONIER'S *Reading at Diderot's* belongs to Baron EDMOND DE ROTHSCHILD and not to Baron GUSTAVE, his brother. The full-sized portraits by REMBRANDT, two of the master's *chefs-d'œuvre*, which were in the celebrated Van Loon Collection in Amsterdam, came directly into the collection of the Baron GUSTAVE DE ROTHSCHILD. They represent Willem Daey (SMITH, "Catalogue raisonné," vol. vii., page 122, No. 340) and Meijfvrrouwe Daey, his wife (SMITH, vol. vii., page 176, No. 551). MEISSONIER'S "1814" belongs to M. CHAUCHARD, and was never in the Duc de MORNAY'S gallery.

THE competition for the new public baths and wash-houses for St. Marylebone has been settled. On the recommendation of Mr. CHARLES BARRY, the assessor, Mr. JOHN JOHNSON, 9 Queen Victoria Street, E.C., has obtained the first premium of 100*l.* The second prize of 60*l.* was awarded to Mr. A. SAXON SNELL, and the third of 40*l.* to Messrs. ARDRON & CHEERS. The premiated designs can be seen at the Vestry Hall, Marylebone Lane, W.

THE one hundred and fortieth annual meeting of the Society of Arts was held on Wednesday, Sir HENRY DOULTON, vice-president of the Society, in the chair. The Prince of WALES was re-elected to the Presidentship, which office he has filled since 1864. The new vice-presidents elected were H.R.H. the Duke of YORK, the Earl of ROSEBURY, Lord HALSBURY, and Sir COURTENAY BOYLE; the new members of council were Captain ABNEY, Mr. WOLFE BARRY, Lord BELHAVEN, and Mr. A. SIEMENS. The report, which was read by the secretary, Sir HENRY WOOD, summarised the work of the society for the past year, and referred specially to the Chicago Exhibition, for which the Council of the Society had acted as a Royal Commission.

REYNOLDS AND THE BOLOGNESE SCHOOL.

THE admiration which Sir JOSHUA REYNOLDS so often expressed towards the CARACCI and their followers has been a surprise to many readers of the "Discourses." It is, however, easily explained. HAYDON and many other critics imagine that the first president of the Royal Academy was not sincere when he was addressing students on the subject. They say his teaching was not confirmed by his practice. According to them REYNOLDS had only one idol—TITIAN—but he took care to keep his idolatry to himself. It is not always a teacher's duty to set up his own conduct for imitation, for he may feel that he has been unwise in adopting a creed or that the belief which seems congenial to himself is not adapted for novices. For a portraitist of genius TITIAN's works were invaluable, but the founders of the Academy had not the intention of restricting British art to that class of production. The Bolognese examples on the contrary were adapted to be set before young portrait-painters and landscapists as well as before painters of history pieces. They might be described now (although the phrase would not be understood in the last century) as "all-round" models. They were excellent in drawing, composition and colouring beyond the majority of the works of the Italian masters, in fact they were only surpassed by RAPHAEL's, which might be considered as unattainable in this country. The sonnet which AGOSTINO CARACCI composed about the aims of the Eclectic School is suggestive of insipid concoctions, but it expressed the kind of things which teachers of all kinds like to set up for imitation. To say to an embarrassed artist who is anxious to obtain the money that will pay the rent of his studio with the least delay, that he must endeavour to combine in his picture the design of Rome, the chiaroscuro of Venice, the dignity of Lombardy, the terrible animation of MICHEL ANGELO, the nature and truth of TITIAN, the purity of CORREGGIO, the symmetry of RAPHAEL, the decorum of TIBALDI, the invention of PRIMATICCIO, mixed with a little of PARMIGIANINO's grace, is a sort of cookery-book recipe for the production of indigestibilities. But all the ingredients are excellent in themselves if enjoyed singly. The CARACCI went nearer than most men in making a combination of them, and their products have their use if only as warnings. We might compare the Bolognese pictures to the headlines which are set before students in calligraphy. The moral sentences of the copper-plate engraver are too finely executed for everyday use; nobody who employs his fingers in a manly occupation could ever hope to write in that way. But the engraved lines probably have saved compositors, experts in handwriting and receivers of letters a good deal of trouble in making manuscripts less illegible.

A schoolboy who can employ graceful curves and firm lines resembling the engraver's will, when he has had practice in correspondence or office work, modify them and gain a style of his own. As we take it, REYNOLDS recommended the imitation of the CARACCI with a similar object in view. He did not wish the students of the Academy to persist in a mimicry of the Bolognese artists during their lives, but to employ the style as a sort of restraining force against an immature individuality which was likely to be marked by excesses. That view is suggested by what he says in his second discourse:—"Style in painting is the same as in writing—a power over materials, whether words or colours, by which conceptions or sentiments are conveyed. And in this LODOVICO CARACCI, I mean in his best works, appears to me to approach the nearest to perfection. His unaffected breadth of light and shadow, the simplicity of colouring, which, holding its proper rank, does not draw aside the least part of the attention from the subject, and the solemn effect of that twilight which seems diffused over his pictures, appear to me to correspond with grave and dignified subjects better than the more artificial brilliancy of sunshine which enlightens the pictures of TITIAN; though TINTORET thought that TITIAN's colouring was the model of perfection and would correspond even with the sublime of MICHEL ANGELO, and that if ANGELO had coloured like TITIAN, or TITIAN had designed like ANGELO, the world would have had a perfect painter." In these words the President appears to speak as a teacher rather than as an artist who was revealing the qualities he sought after in his own works.

REYNOLDS must also have known that if the CARACCI expected to form a body of imitators when they set up their school they were doomed to suffer disappointment. The Bolognese school is inferior to all the other Italian schools in some desirable qualities, but it surpasses them in the variety which was exhibited by disciples that were supposed to be examples of fidelity to the founders of the school. The composite nature of the system would at any time lead to that result. If instead of "un po' di grazia del PARMIGIANINO" a larger modicum of grace were introduced the difference would be apparent, and the relative quantity of any of the other elements would make one picture orthodox according to Bolognese canons and another have an opposite character. The most faithful imitation in painting is not always taken to be virtuous. DOMENICHINO's *Communion of St. Jerome* in the Vatican corresponds with the *Confession of St. Jerome* by AGOSTINO CARACCI. But instead of accepting the picture as a proof of the loyalty of a pupil towards a master to whom he was indebted, the world has looked down on it despite its great merits as a revelation of the weakness of the painter, who made himself a tool of ANNIBALE CARACCI at a time when that artist was jealous of his brother on account of the success of the *Confession*. It would therefore be absurd to suppose that REYNOLDS could have desired to see the English Academy become a sort of foreign branch of the Bolognese school.

There was likely to have been another reason for REYNOLDS's admiration. The effort which the CARACCI made in Bologna was not altogether unlike the experiment in which the Royal Academicians were engaged 170 years afterwards in London. In England the system of pupilage was declining when the Academy was founded in the eighteenth century. It was supposed a substitute would be found in the new schools. The old system of pupilage or apprenticeship which had lasted so long in Italy was overturned by LODOVICO CARACCI. He was a slow, patient, ruminating artist, and his rivals nicknamed him "the Ox." There was in him none of the swagger, presumption, or self-sufficiency of the earlier artists. TINTORET could not discern any talent in him, and advised him to abandon painting. LODOVICO believed, however, that perseverance could compensate for many defects, and when he found he was not made competent in Venice, he tried his luck in Florence and Parma. He was no believer in the supremacy of any artist of that time, which denotes his shrewdness, for the decline was then prevailing, and, as became a contemporary of FRANCIS BACON, he tried to raise the superstructure of art on the foundation of science by a rigorous comparison of the qualities of pictures by a variety of masters and an investigation of their principles. There were no idols of the school for LODOVICO. Returning to Bologna he persuaded his cousins, AGOSTINO and ANNIBALE, to follow painting, and as soon as they were grounded in the elements of art he sent them to Parma to study the dome paintings of CORREGGIO, and to Venice. AGOSTINO was versatile, and is more likely to be remembered by his sonnet and engravings than by his pictures. ANNIBALE was endowed with finer abilities by nature than either his brother or cousin, and his paintings are the best exemplification of any virtue which eclecticism may possess.

The people of Bologna were not willing for a time to admit that the CARACCI were as competent to paint as their contemporaries. It was not an age when self-instruction was considered feasible, and apparently it would have been hard to discover an artist who was willing to testify to the ability of the reformers. It was not until LODOVICO had demonstrated in a room of the Fava Palace how well he could compete with any of the artists of the city that he was recognised as a painter. Then the relatives opened their academy, in which AGOSTINO became the principal teacher. They obtained drawings, engravings and casts from the antique for the instruction of the students, the living model was introduced, and lectures were given on composition, criticism, architecture, &c. There were also periodical fêtes. But with all its advantages and attractions, it is doubtful whether the *Incamminati*, or Academy of Progress, met with immediate success. DENIS CALVART, CESI and FONTANA were then the representatives of the old system in Bologna, and their pupils had to sacrifice prejudices and go over to the new school before it could be considered as established. It is said that the principal objection which

CALVART raised against the new system was on account of the importance attached to the study of nature. There could be no stronger proof that the CARACCI did not begin their innovations too soon. That their system of teaching was effective is seen in the success of pupils, for among them were DOMENICHINO, ALBANO, the two MOLAS, GUIDO, GUERCINO, LANFRANCO and TIARINI. Those artists differed in their manner of painting, but they all agreed in avoiding the contorted figures which were supposed to be a testimony of homage to MICHEL ANGELO.

REYNOLDS could not approve of the disregard of the great Florentine, but other practices of the school would recommend themselves to him and to other lovers of a safe course. The Bolognese school represented compromise as well as eclecticism, and was therefore adapted to the circumstances which surrounded the infant academy in London. As much success as was gained by the students who listened to the CARACCI would have appeared satisfactory to King GEORGE and his advisers.

It would perhaps have been preferable if the President could have informed the students that, whatever was the case with the Greeks, the greatest painters of the Renaissance and the later period were not remarkable for that balance of qualities which the CARACCI were supposed to attain. The great painters from whose works certain attributes were supposed to be derivable carried those attributes to excess. The verity of TITIAN, the harmony of RAPHAEL, the ornamentation of TIBALDI were not stingily measured, they were given out liberally, and on that account have been prized. It is strange that the CARACCI, when preparing their recipe and advising a selection of various qualities, did not perceive that, however logical might be the result, it would not be captivating. In the mineral kingdom it is possible to find gems that are entirely perfect, mathematically exact in planes and angles, but in the organic world nature is indifferent to uniformity of that sort, and according to our human standard a natural scene or object never becomes sublime until it displays exaggeration on an unusual scale. It may be admitted that the imitation of the works of great artists is attended with more danger than the imitation of eclectic examples, because any excess in the former is certain to be magnified in the copy. Eclectic examples, on the other hand, are so subdued throughout, having so little about them that is mannered, that they seem to be adapted to become a sort of basis on which individuality can assert itself. Mechanical science is founded on geometry—that is, on notions of points that have no parts, lines without breadth and surfaces without thickness. But it is none the less practical on that account. REYNOLDS and his friends may have concluded that a corresponding result could be gained in painting by starting from the works of the Bolognese school, which come nearer to abstractions than the majority of paintings of any age or country. They had also the advantage of being a sort of “elegant extracts,” for in many of the pictures by the CARACCI there is no difficulty in perceiving that the admiration for other masters was expressed by employing some of their figures. By a study of those pictures a student is therefore made acquainted with parts of infinitely greater works. These reasons seem to us to justify all that REYNOLDS has said on the subject.

THE MECHANICS OF ARCHITECTURE.*

BUILDING Acts and by-laws have made it less imperative for an architect to be guided by mechanical principles. The prescribed dimensions have at least the advantage of guaranteeing stability. But authority, after all, has only given sanction to rules which experience had established. Whatever may be the shortcomings of English buildings of the cheapest class, they are at least likely to endure, and that fact should gain respect for those who first established the allowances for safety. It is rare to hear of the collapse of a jerry-built house in a storm. Examples of the same sort of construction are often utilised for purposes which were not contemplated when they were erected, and

which impose greater strains on the materials. Yet somehow they manage to survive. A Cambridge Wrangler, if he applied his scientific knowledge in overhauling the plans, could not achieve a more satisfactory result. It would be more likely that his conclusions (assuming them to be substituted for the old-fashioned rules) would not be conducive to permanence or safety. The Tay Bridge catastrophe will always be a reminder to those who imagine that acquaintance with theoretical mechanics can make a man infallible when he designs a structure. It should also be remembered that the materials which are readily obtainable in the market must also affect the calculations that are based on scientific principles. In German books of construction there are abstruse investigations of such subjects as the diameter to be given to the piping for gas in ordinary rooms or for the water-supply of a small house. But it is not to be expected that lead or iron pipes will be found that will correspond exactly with the bore which was ascertained by calculation to be the fittest. There are also theorists who conclude—perhaps we ought rather to say who imagine—that the web in rolled girders is far too thick. Whether that assumption is right or wrong, we need not consider; it is sufficient to say that in rolled beams, as in cast-iron beams, the necessities imposed on the manufacturers must be respected.

All that can be accomplished by either mechanical or chemical science in building is so limited that it rarely warrants a departure from established ways. In fact, it will generally be found that, when failures arise, their origin is to be traced to conclusions which were derived from theory, and which were not confirmed by experiment or experience.

Although it can have only a modest sort of relation to building practice, theory should not be neglected. In the first place, it imparts the satisfaction which is always felt when we can perceive principles in common objects. Then it has the advantage of inspiring scepticism of rules which, however satisfactory in general, may be inadequate to serve a particular case. Without theory, construction cannot be well explained, and it is difficult to understand how the Byzantine and Mediæval builders, who must have had only a rudimentary theory of mechanics, were able to persuade the clergy to allow them to undertake daring feats of construction. As faith prevailed, we suppose the master of works was allowed to do what he pleased. According to Mr. TARN, the thrust of the semi-dome in St. Sophia amounts to 125 tons, and the thrust of the dome is 450 tons. By what means did ANTHEMIUS, ISIDORUS or IGNATIUS convince the emperor that the walls and semi-domes were equal to meet so much power? In our time the problem could be easily explained.

In his exposition of the theory of mechanics as applied to St. Sophia, Mr. TARN is careful to say he is only aiming at an approximation of the actual thrusts. The word suggests one important quality in his book. Mr. TARN does not write merely as a mathematician; he is careful to suggest the limitation of the science in whatever relates to practice. That sort of care is more necessary in dealing with mechanics as applied to architecture than in engineering cases. The engineer relies mainly on iron and steel, which may be considered as being uniform in their qualities. A conclusion arrived at in one case will therefore be generally applicable. But when natural materials are employed without undergoing a process of transformation there is unfortunately less certainty, and ultimate strength must be considered as having a more or less remote relation to what can be borne in safety.

Mr. TARN, besides those on the general principles of mechanics, has chapters treating of beams, including flooring, pillars, roofs, trusses, arches, domes, spires, buttresses, shoring, retaining walls, foundations, piling, effect of wind on buildings. Appended are several problems which comprise typical cases with solutions. Like the other books by the author, “The Mechanics of Architecture,” if carefully studied, will have a disciplinary value, and will impart new interest to construction. It serves a purpose for which standard works like RANKINE’S, STONEY’S and WEISBACH’S were not sufficiently special.

* *The Mechanics of Architecture: A Treatise on Applied Mechanics, especially adapted to the Use of Architects.* By E. Wyndham Tarn, M.A. Second Edition. Crosby, Lockwood & Son.

Mr. William Dunn, M.P. for Paisley, presented the town with a public garden. The grounds are situated in the centre of Paisley, and have cost the donor some 9,000*l*.

ROYAL INSTITUTE OF BRITISH ARCHITECTS.

THE concluding meeting of the session of the Institute of Architects took place on Monday evening, Mr. F. C. Penrose, president, in the chair.

The decease of Mr. W. Calder Marshall, R.A., was announced.

A resolution submitted by the President and supported by Mr. Charles Barry was passed spontaneously, viz.: "That the Royal Institute of British Architects desires to be associated with the Central Society of French Architects in an expression of the horror and indignation with which the news of President Carnot's mournful death has been received, and to offer on behalf of British architects at home and beyond the seas respectful and sympathetic condolence with their colleagues in France in the horrible calamity of last night."

The President's Address.

The President in the course of his address said:—We have now before us a much more grateful task, and one in which I feel it to be a high privilege to take a share, in presenting, in the name of our gracious patron, Her Majesty the Queen, the gold medal to one who has greatly honoured us by accepting it at our recommendation. The distinguished president of the Royal Academy is well known to all of us here by his works and by his renown, and to many by his friendship, and his genial courtesy to all who have had any intercourse with him.

Sir Frederic Leighton was born at Scarborough, and his natural inclination towards the graphic arts early declared itself. His father, a physician, though he had other views for his son—intending it is said to give him a University education, with a view to his ultimately being called to the Bar—nevertheless encouraged him to make himself acquainted with anatomy, and gave him every facility for the study of art in order that he might be equipped for the profession should he eventually follow it. We early find him, then, studying at Rome; and, if I may be allowed a moment's digression, this leads me to reflect that I must occasionally have fallen in with him during the winter and spring months at the Artist's excursion called the Cervara, or on the Pincio, or when it was the ambition of the British art students who were there to fall in with John Gibson at his early coffee at the Lepre. Dr. Leighton became so far a convert to his son's wishes as to consent that the latter's drawings should be submitted to the celebrated American, Hiram Power—a man not less remarkable for his great skill as a sculptor and his knowledge of art than for his noble physique, his courteous manners and his sterling character—and if he decided that there was the true artist's ring about these works, his son should no longer be opposed in following the bent of his inclination. We may, I think, appreciate the pleasure which the good American had in assuring the father that there could be no doubt whatever on the subject. The pithy way in which old Hiram Power gave his verdict is worth recording: "Then you think," said Dr. Leighton, "I ought to let my son be an artist?" to which there came the answer—"You have no choice, sir; Nature has done that already." After this the youthful painter studied in various European centres, and made himself proficient, not only in the art of the countries in which he sojourned, but also in the languages, as those who have heard him discoursing with foreigners can testify. At Brussels, when eighteen years of age, he produced his first finished picture, *Cimabue Finding Giotto in the Fields*. He shortly afterwards showed his sympathy with our profession by a painting of which the subject was the death of Brunellesco. After some residence in Paris, working at the Louvre, he studied at Frankfort under the painter Steinle, to whom he submitted the design of his magnificent picture *The Triumph of Cimabue*, which he carried out at Rome. I have heard that during this period Thackeray fell in with him and prophesied that, although as yet altogether unknown in England, he would become president of the Royal Academy. The picture above referred to was sent to England for the Exhibition of 1855, then held in the rooms of the National Gallery. The picture was immediately bought by the Queen. But, for the present renouncing what might have seemed a lucrative opportunity for accepting work in London, he returned to his studies, and resided for some years on the Continent, chiefly in Paris, in communication with some of the most distinguished painters of that capital. Soon after his return to England, he painted the fine fresco representing *The Five Foolish Virgins*, in the church at Lyndhurst, in the New Forest; and in the same material, but more recently, two large fresco paintings at the South Kensington Museum, representing the Industrial Arts applied to Peace and War. It is, however, impossible in the space here available, to enumerate anything like a list even of his principal paintings. *The Power of Music* was exhibited in 1856. The classical subject of *Hercules Wrestling with Death for the Body of Alceste* must be specially mentioned, for it called forth the praise of his

friend Browning in the poem called "Balaustion's Adventure":—

I know, too, a great Kaunian painter, strong
As Herakles, though rosy with a robe
Of grace that softens down the sinewy strength,
And he has made a picture of it all.

More lately we have seen the fine, pathetic picture of Andromache, *dejectam conjuge tanto*, in her captivity. In 1881 the merited compliment was paid him in the request from Italy that he should contribute his portrait to the gallery of distinguished painters in the Uffizi at Florence. Not content with the triumphs of his brush, he has invaded the sculptor's domain. In 1877 we admired the fine group of the *Athlete Struggling with a Python*, and in 1886 his bronze statue of *The Sluggard*. I shall presently have to speak of his potential claim to graduate in architecture. Up to 1883 he had for many years, as their colonel, led the Artists' Corps of Volunteers. His eloquence in presiding at the Royal Academy dinners is the theme of all. The social side of his character is equally admirable, and many are those who can bear witness to generous actions on his part, both in purse and kind sympathy. I do not suppose there is any one in this room who questions that the Institute has been thoroughly right in making the award of this medal which we have the happiness of bringing to its consummation to-night; but, in case there should somewhere be a doubter, I will make a few remarks on that head. Had Sir Frederic Leighton no other claims upon us than the noble architectonic works that have often been products of his hand, works, many of them in oil and fresco, executed for the embellishment of public and private buildings, the Institute would have a perfectly good answer to give. The late Prince Consort thus defined the ruling principle—namely, that the appropriation of the Gold Medal should be left an open question to be raised according to circumstances in each year, and to be applied as the Council might periodically feel to be the best for the general interests of the profession. The Institute would therefore be justified in awarding the medal to an artist of high distinction either as a painter or sculptor. But Sir Frederic Leighton is very much more than a painter. He is the only President of the Royal Academy, from the time of its first foundation, of whom it can with certainty be said that he has evinced a thorough knowledge of all the great arts, and who is practically great as a painter, a sculptor, an orator and a writer.

The greatest master in art since the days of Pericles is reported to have said, "I know but of one art." There have been but few who could justly adopt those words, but one of those few is Sir Frederic Leighton. Similar to its tripartite analogy in nature, where length, breadth and thickness form one space, so architecture, sculpture and painting are one in art; the practice is different, but the principles, whenever excellence is touched, are found to be the same in each branch. You know Sir Frederic Leighton's high achievement in sculpture. In architecture there is the clearest evidence of what I have called his potential merit had he had occasion to practise in our special branch.

In biennial addresses to the students of the Royal Academy, particularly in the years 1889, 1891 and 1893, we find criticism of the highest value clothed in beautiful language on the Spanish, French and German schools of Mediæval architecture. Not mere sketches and generalisations, but dealing with the subject in an exhaustive manner. Our ex-President has most happily and justly eulogised these addresses in his discourse to students at the beginning of this year.

That an artist of such refinement would also be in sympathy with the spirit of Classical architecture will not be doubted. I had myself frequent opportunities of bearing witness to his appreciation of the elements of beauty in the works of the Greeks at meetings of the Publication Committee of the Society of Dilettanti; but I wish particularly to call your attention to the masterly summaries of the characteristics of Mediæval architecture as practised by the leading races of Continental Europe in the Academy lectures before referred to. The whole series is full of practical teaching in clear and incisive language, but as in this address limitation is necessary, I will confine myself almost entirely to what is said on the evolution of Gothic architecture from its source at St. Denis. After a short discussion of the earlier manner of vaulting from the Roman type, in which stability for the waggon vault was sought in the resistance of solid masses of brick and concrete work, we read:—

"The substitution of the principle of a balance of active forces to this principle of inert resistance is probably the greatest revolution ever introduced in the science of building; we have here the generative principle of Gothic architecture, its essence and its life. How this revolution was brought about I can of course only indicate to you in summary outline. Let us first note in passing that the presence of a pointed arch, except as a structural form, does not constitute Gothic architecture. Isolated radiating pointed arches have been built in ages and countries in which the Gothic style was not dreamt of; a building might be Gothic in structure and principle without showing a pointed opening anywhere; it is through the

roof, not through the window, that the formative Gothic idea entered."

Then, after describing various expedients for securing stability, including the important step taken at Vezelay, where intersecting vaults, but without ribs, were substituted for the continuous waggon-head—an advance, but not yet satisfactory—we read:—"A few years later, in the early middle of the twelfth century, a Benedictine monk, feeble of frame, but of a lofty spirit, Suger, the great Abbot of St. Denis—who has on sculptors, by the by, this special claim, that he boldly withstood the bitter denunciations launched by St. Bernard against the sculptural decoration of churches—began the erection of a church in which the tentative gropings, at which I have just hinted; gave place to the systematic and logical application of a new and fruitful conception—the idea of stability based on the balance of active forces, expressed in a self-sustaining combination of upright supports and vaulting ribs, with detached buttresses bringing their action to bear exactly on the points at which the thrust of the vaults is gathered up."

The address concludes:—"Is there any lesson that we may draw from this hurried survey of artistic evolution among the French? I have dwelt with emphasis on the genius of their Mediæval builders; do I advocate—the young architects for whom I have mainly spoken to-night may ask—do I advocate the adoption of Gothic forms for the purposes of our own lives? I have spoken to little effect if my answer can be doubtful. Artistic forms are the vesture of ideas and the expression of mental conditions; the ideas and mental conditions of our day are widely removed from those of the Middle Ages; the modern mind cannot with fitness put on the garb which was moulded on the mind of a day long past. But if we may not fitly adopt those forms, we cannot too reverently note the spirit which presided over their development, for a like spirit brought to bear on other material and under other conditions may yet bear new and noble fruit. And the characteristics of that spirit are a masculine independence, a tenacious grasp of central principles, a fearless sincerity in expression, a scorn of shams and trust in truth."

In Sir Frederic's address for last year we find admirable criticisms on the German Mediæval architecture; praise where due is given to the German Romanesque, and afterwards the reflection, which appears to me perfectly just, that the Germans as a race were never in unison with Ogival architecture; and in respect to their great achievement—Cologne Cathedral—though not withholding praise, he observes, as I think most truly:—"We feel that we are in the presence and under the spell of a powerful will, grasping serenely and solving with unflinching and intellectual resource a scientific problem; we bow accordingly before a triumph of skill and volition; we are not, as it seems to me, thrilled by the kindling touch of genius."

To the pictorial works by Sir Frederic Leighton in connection with architecture already named may be added paintings for the ceilings of a house at New York, of which our gold medallist, Mr. R. M. Hunt, was architect, as well as several of the same character in London. But I must specially mention one work combining architecture in the solid, with which he has had much to do. I allude to the removal of Alfred Stevens's monument from the south chapel in St. Paul's to the nave for which it was originally designed, which was done entirely under his inspiration and in no small degree at his expense. I feel sure that there can be no need for me to dilate further on what seems to require no argument in justification of the action of our ex-President and of the Council, and of the Institute which has ratified their action in awarding this medal, especially when, to the great advantage of the Institute, Sir Frederic Leighton's acceptance of it sheds lustre on the roll of medallists, so well begun with the loved and honoured name of Professor Cockerell, and it must be obvious to all of us that the whole profession gains from the fact that the chief representative of art in its three branches in this country thereby shows how much he is in sympathy with architecture.

The PRESIDENT then presented Sir Frederic Leighton with the Royal Gold Medal.

Sir F. LEIGHTON, in returning thanks, said he wished to express how deep and warm was his sense of the honour he had received—one quite unique, as he understood it was the first time that honour had been conferred on a painter, an honour to which the President had added so much grace by his words. In regard to an ancient and noble craft it might be said that enthusiasm and sympathy were contagious. In some small degree he hoped that he had rendered some service, by word if not by deed, to the spreading of the atmosphere of favouring interest in which every creative effort best thrived and prospered. Alluding to the three arts, he said no one would deny that the co-operation of the arts had bestowed on the world many of its choicest masterpieces, such as the House of the Virgin Goddess at Athens, Chartres Cathedral, and St. Mark's of Venice. Neither was it open to challenge that great advantage must accrue to the followers of architecture, painting, and sculpture from a knowledge of and sympathetic insight into the nature of each art,

and the fundamental affinities which united them. On the other hand, the fruitfulness of solidarity between them had led to no little misapprehension as to the true character of their relationship. The subordination of painting and sculpture to architecture was a short-sighted fallacy, revealing but a scant appreciation of that house of many mansions—the house of art. Even in the face of architecture, the arts of which the theme was man, and the myriad-mooded aspects of the outer world, stood unabashed, even among the children of the greatest architects the world had ever known. In early Mediæval days, when the building was the book, the open volume on which alone could be read by an unlettered people the truths of faith, and that little which was then the sum of knowledge; in the days before the printing-press had shorn architecture of half its phonetic function, some such contention on its behalf was no doubt tenable. But in more modern times great changes had come over art, and notably over painting, which, without abbreviating its severe and more restrained function in connection with architecture, or its most ornamental developments, had explored and occupied whole regions of new, emotional and imaginative suggestions—the realms of mysterious and alluring glooms, wherein Rembrandt was king, and all the witching range of the fugitive and fitful lights which flitted and flamed, and fainted across the fair face of the sea and of the land in which Turner conjured without a peer.

In these its phases the painter's art was self-centred and unobeholden. He had more than once been asked to express his views on architecture from the painter's point of view. His answer had always been, in substance, that architecture was an art of which the conditions were unique as well as imperative, and knew no determining artistic motives outside itself. These conditions were the rigorous fulfilment in each case of the demands of a dictated problem of utility, of which the result was a structure stamped with the expression of its functions, lit up and ennobled throughout by the spirit of beauty. Whilst in fruitful intercourse Architecture might gain a heightened charm and a warmer and more supple life, how great was the service that she might in her turn, if rightly consulted, confer on the other arts, for where better than in her best and purest works could the painter and the sculptor learn the great and needed lessons of wise restraint, of noble reticence, of thought controlled, and of ornament made doubly precious by sober use—of a truth these three arts might draw ever-increasing strength and power from closer communion of spirit among their several votaries, and it was a symbol of that growing communion that even those who might least deem him worthy of it, might yet welcome the honour for which he expressed his warm, respectful, and most unfeigned thanks.

The meeting then adjourned till November 5.

EXCAVATIONS AT ARGOS.

THE following account of the exploration of the site of the sanctuary of Hera in Argolis by the members of the American School at Athens, working under the direction of Dr. Waldstein, has been given by Mr. E. Robinson, of the Boston Museum:—

The site of the Heraion is literally one of the most commanding that could be thought of for a temple. No one who has crossed the plain of Argos can ever forget the beauty of that country. More level than Attica, its appearance is also more restful. There is hardly a mound to break its surface until one reaches the foothills of the mountains which surround it, except where the sea makes its crescent on the south. Almost hidden in the north-west corner stands the citadel of Mykenæ, commanding the whole district without being itself conspicuous. To the east of this runs a wall of low mountains, which forms the northern boundary of the plain. One of these, Eubœa, stands out a little more prominently than the others. The long, sweeping curve of its slope is broken near the base by a small crest or ridge, into which it rises just before it joins the plain, and this crest was chosen as the site for the temple of Hera.

The original temple was placed, not upon the summit of this crest, but upon the upper part of the southern slope, where a platform or terrace was constructed for it, and here it must have formed a conspicuous object from every quarter of the plain. The huge rectangular blocks, of which the retaining wall of this platform was built, were for years the only landmark of the site, until in 1852 Rangabé excavated sufficiently to locate the position of the late temple, of which I shall speak presently. The platform itself was buried to a considerable depth under accumulated soil, until the present excavations laid it bare and determined its limits. It is paved with polygonal blocks, and measures about 148 feet in length by 115 feet in breadth. Its situation, in reference to the other buildings of the sanctuary, is shown on the plan which accompanies the twelfth annual report of the school issued this spring. Unfortunately very slight remains of the temple were found, a cir-

cumstance easily accounted for by the probability that, above the base line, it was constructed of clay and wood, like the Temple of Hera at Olympia. Even the columns have disappeared, and the only unquestionable remnant on the site is a portion of one low wall, on the top of which the circles traced in the stone to indicate the size and position of several of the columns are still clearly visible. This bit of wall is much more primitive than those of the Olympian Heraion, and bespeaks a decidedly earlier date for this temple, which may therefore be the oldest Greek temple that we know. Possibly there may be other data concerning it among the *debris* of the excavations in other parts of the hill, but this is a matter for an expert architect to determine. The pavement of the platform is in remarkably good preservation. Above it, and separated by a thin layer of earth, was a concrete flooring, several patches of which are left. Some of these are blackened by fire, presumably the conflagration of which Thucydides speaks, by which the temple was destroyed in 423 B.C.

Of the later and more famous temple the remains are much more satisfactory. The Greek prejudice against erecting a new temple upon the site of an old one is well illustrated here. Instead of utilising the old platform, which was perfectly able to hold it, a second terrace was constructed below it, also on the southern slope and overlooking the plain. I say a second terrace, yet it would be more correct to speak of this as the third, there being a smaller one between the two, upon which many remains of early houses have been found. These are described by Dr. Waldstein in the report to which I have alluded. As he suggests, they probably had some connection with the service of the older temple, and were possibly the dwellings of the priestesses. The excavation of the later terrace is a remarkably clean piece of work, and reflects great credit on those who had to do with it. Every answer which the place still had to give as to the character and details of the new temple and its immediate surroundings the student finds here readily at hand. On this terrace there is nothing more to be uncovered, and evidently no fragment that could have been of the slightest importance has been thrown away. If it is lost, the manner in which the site has been unearthed is sufficient evidence that it was lost before the excavations were begun. What actually remains *in situ* is the walls of the foundations, several courses high, including those of the peripteros and the interior, and that of the steps or incline by which the temple was entered. These foundation walls are not preserved up to the level of the floor, and from the manner in which they were left it is evident that they, and probably other portions of the temple, were not destroyed by nature or by violence, but carried away block by block. There is reason to believe, therefore, that the careful examination by an architect of the towns in the plain might result in the discovery of important pieces built into Mediæval or later structures. On and near the terrace are sufficient fragments to give the general indications of the proportions and style of the temple, though here again it is surprising that there are not more. I believe that only three fragments of capitals have been unearthed, and scarcely any of the columns themselves. On the other hand, a number of blocks of the upper members have been found, and these show that both the triglyphs and the background of the pediments were of black marble.

The retaining wall which separated the terrace of the later temple from that above it formed the back of a long stoa or portico, in front of which votive statues and stelæ were erected. The bases and grooves showing where these stood are numerous, but, beyond a few inscriptions, nothing of the works themselves remains.

Below the new temple is a fourth terrace, which seems to have been occupied for the greater part, if not the whole, of its length by another portico, only a portion of which has yet been uncovered. The greater part of the working force has been concentrated upon this site during the present season, partly because it seems to have been one of the principal buildings of the sanctuary, and might be expected to contain inscriptions or other monuments of importance, and partly because Dr. Waldstein hoped that in the enormous mass of earth under which its remains are buried he might find sculptures or other valuable objects thrown over from the terrace of the temple. Some fragments of metopes have already been found here, and quantities of terra-cotta fragments. But not more than half of the portico had been uncovered when the work had to be brought to a close, and we cannot say what may yet be waiting to be brought to light.

Of the sculptures the now famous Hera head still remains the most beautiful and the most interesting. Of this and the other fragments which are now familiar in America through casts and photographs I need not speak. This year, besides the fragments found on the lowest terrace, several have been brought to light elsewhere, among them the head of a youth which bears a close resemblance to the female head found by Rangabé on this site. This year, as before, the fragments of decorated pottery discovered are almost countless. Combined they form one of the most remarkable finds of this nature ever

made in Greece. By far the larger part of the early styles, Mykenæan, Dipylon, and, most of all, the so-called "proto-Corinthian," upon the history of which they bid fair to throw new light. The labour of classifying these will be long and trying, but it will give our school one of the best opportunities that could have been desired for publishing new and valuable material.

Speaking of pottery, I cannot pass over a most interesting discovery which took place while I was at the excavation—that of a "beehive" tomb of the Mykenæ type, which apparently had never been open since the last body was placed in it. The excitement of watching an event like this cannot be described, and it is felt by the workmen no less than by those who are superintending them. First of all, the discovery that there is a tomb, a discovery possible only to the expert digger (in this case a workman), whose practised eye detects in the slight depression of the soil the fact which another would pass over without suspecting. Then the beginning of work with the pick and spade. Slowly the truth comes to light, the tomb was roughly hewn in the soft rock, and the top having fallen in, the vault or chamber is filled to the surface with a solid mass of earth. Gradually its concave walls show themselves, and then the two or three men who can work inside the hole proceed, as carefully as their impatience will allow, to clear the interior down to the level where they may expect to find something. After a time—and a long time it seemed—the first indication comes. The fragment of a human bone is struck. Now the pick and spade stop, the men get down on their knees and scratch the earth with their knives, working as delicately as Italians. Presently one of them utters an exclamation—the first vase has been found. It is a decorated specimen intact, and shows that there is hope for more. In this way the work continued for two days, at the end of which the tomb and its *dromos*, or entrance passage, had been cleared out. The tomb measured about 10 feet in diameter and the same in height. It contained no less than fifty-two specimens of prehistoric pottery, most of them fine examples of the Mykenæ and Ialysos types, with the decorations upon them quite fresh and brilliant. Of these forty-eight were vases, three were idols and one was a little chair or throne for an idol, about 6 inches tall and gaily painted. There was no metal of any kind.

TESSERÆ.

Salisbury Spire.

THE spire of Salisbury Cathedral is believed to have been added when Robert de Wyvile was bishop, a prelate of whom this ugly character has been transmitted to posterity, that it was hard to say whether he was more dunce or dwarf, more unlearned or unhandsome. While he held the see, a mandate was obtained from Edward III. for taking down the walls of the former cathedral at Old Sarum, and of the houses there which had belonged to the bishop and the chapter, that their materials might be applied, as the king's gift, to the improvement of the church at Salisbury. Not only the spire, but the two upper storeys of the tower were added when these improvements were made. This was so bold an undertaking in the architect that nothing but success could justify it. Michel Angelo's conception of hanging in the air the dome of St. Peter's did not imply a stronger confidence in his own skill than was manifested in this ambitious design of raising one of the loftiest spires in the world upon a building where the foundations had already received the load which they were calculated to support. The old wall of the tower, though strong enough when it was the summit of the pile, was slight in relation to the weight which it was now to bear. Half its thickness was occupied by an open gallery, and moreover it was perforated by eight doors, eight windows, and a staircase at each of its four angles. For the purpose of strengthening it the windows were filled up; 112 additional supports were introduced into this part of the tower, exclusive of iron braces; and 387 superficial feet of new foundation were formed. It is presumed also that at this time the arches and counterarches were raised across the small transept. The difficulties were so evident and so great that it has been said they were enough to have frightened any man in his senses from pursuing so rash and dangerous an undertaking. It has, however, withstood the storms and the sap of more than five centuries, and we are told that, if carefully inspected, it may remain twice five centuries to come. Two stories of the tower were evidently raised at the time when the spire was added. From the centre of the tower the spire rises; four of its sides (for it is octangular) resting on the walls of the tower and four on arches raised at the angles. The wall of the tower is there 5 feet thick, two of which are occupied by the base of the spire, two by a passage round, and one by the parapet. The wall of the spire gradually diminishes till, at the height of about 20 feet, it is reduced to 9 inches, of which thickness it continues to the summit. A settlement took place in this beautiful structure, it

is believed, soon after its completion, at the western side, or rather in the piers or clustered columns, under the north-western and south-western angles of the tower. Such methods as were deemed best have been employed at different times to counteract the danger. At the top of the parapet of the tower, the tower declines 9 inches to the south and more than 3 to the west; but at the capstan of the spire the declination is 24½ inches to the south and 16½ to the west. In such an elevation this is not perceptible to the most practised eye, the height being 404 feet, according to the most approved measurement. That of Strasburg is 456; that of Vienna, which exceeds all others, 465; but Salisbury is the loftiest stone building that has ever been raised in this island. The spire of old St. Paul's, which was 520 feet in height, was constructed mostly, if not entirely, of timber and lead.

Ceiling Painting in England.

Rubens received for his painting of the grand plafond at the banqueting-house, Whitehall, the sum of 4,000*l.*, which is little more than 400 yards of work, so that he was paid nearly 10*l.* per yard. This patronage was bestowed in the days of that great encourager of the arts, the unfortunate King Charles. Now our countryman, Sir James Thornhill, received for his laborious and crowded designs on the ceiling at Greenwich Hospital only 3*l.* per yard, and this nearly a century after the painting of Whitehall, when the comparative value of money was so much reduced, and only the sum of 1*l.* per yard for painting the ornaments upon the walls. This employment he was appointed to in the reign of Queen Anne, but the work was not completed until the reign of King George I. He commenced in the year 1708 and finished in 1727, for which he was paid altogether the sum of 6,685*l.* The valuation of the work, after many attempts to screw the painter to a cheaper contract, was made by the directors of the hospital after consulting the following eminent artists, natives and aliens, then practising the art with various success in London—Vandervelt, Cooper, Richardson, Sykes and Degard, who reported in favour of Sir James, that the performance was equal to any of the like in England, and superior in number of figures and ornaments. "The late Duke of Montagu," says Sir James in his memorial to the commissioners for building the hospital, "paid Monsieur Rosso for his salon 2,000*l.*, and kept an extraordinary table for him, his friends and servants for two years, whilst the work was doing, at an expense computed at 500*l.* per annum, which is near 450 yards, amounting to about 7*l.* per yard. Signor Verrio was paid for the whole palaces of Windsor and Hampton Court—ceilings, sides, stairs and back-stairs—8*s.* per foot, which is 3*l.* 12*s.* per yard, exclusive of gilding, had wine daily allowed him, lodgings in the palaces, and when his eyesight failed him a pension of 200*l.* per annum and allowance of wine for life." Rizzi had of the Duke of Portland for three rooms 1,000*l.*; for the little chapel at Bulstrode, 600*l.*; of the Lord Burlington for his staircase, 700*l.* Pellegrini, of the Duke of Portland, for work at his house, 800*l.*, and for a small picture over a chimney, 50*l.*; of the Earl of Burlington, for the sides of his hall, 200*l.*

Rational Criticism.

The uneducated man judges by his feelings; the half educated by rule. He who is thoroughly master of the subject returns again to his feelings, but to feelings trained and purified by study and reflection; and this training of the mind to a true taste for what is good and beautiful is an employment exceedingly pleasant in itself, and conducing to that perfection of the intellect which it is the object of every man to attain. A person who thus criticises every fine building which he sees, without vanity or presumption, with a sincere desire to find out whatever is excellent, and to understand, and fully enter into, the reasons for any admiration which has been generally bestowed upon it by others, yet at the same time not blindly following authority, but bringing everything to the test of his own feelings and judgment, will form to himself a habit, profitable not only when applied to architecture and the other fine arts, but in every subject on which the human understanding is exercised.

Economy of Means in Greek Art.

Who shall say that Greek architecture is poor because its mouldings are few? Seven musical notes have sufficed for thousands of exquisite melodies, and each nation has its own peculiar airs. Who shall count the endless varieties produced by twenty-four letters since language first assumed its written form. "It was not by a multitude of different and isolated impressions," says Dupaty, "that the Greeks sought to interest, to move the feelings and to satisfy the sensibility. They had only one leading idea, and that was a grand one. They repeated it continually, and they modified it much by all the fugitive adaptations of sensible and insensible gradations of which it was susceptible. The Greeks by this means satisfied two singular caprices of sensibility, which, idle and at the same time craving for something new, seeks to retain the same

sentiment and excite a new sensation." To the like effect is the opinion of Milizia, that "the ancients accomplished grand works, as in their temples, by attending to the one great purpose of producing a grand impression at the first glance of a building. They knew not affectation or pedantry. But the moderns are over-scrupulous in minutiae, lose themselves in littlenesses, and consequently too often only accomplish little things without beauty."

Wren and the Balustrade of St. Paul's.

The following reply by Sir Christopher Wren is in answer to the commissioners, who insisted on a balustrade to St. Paul's, none having been originally designed:—"I have considered the resolution of the honourable the commissioners for adorning St. Paul's Cathedral, dated October 15, 1717, and brought to me on the 21st, importing that a balustrade of stone be set up on the top of the church, unless Sir Christopher Wren, in writing under his hand, set forth that it is contrary to the principles of architecture, and give his opinion in a fortnight's time, and if he doth not, then the resolution of a balustrade is to be proceeded with. In observation of this resolution I take leave, first to declare I never designed a balustrade. Persons of little skill in architecture did expect, I believe, to see something they had been used to in Gothic structures, and ladies think nothing well without an edging. I should gladly have complied with the vulgar taste, but I suspended for reasons following:—A balustrade is supposed a sort of plinth over the upper colonnade, which may be divided into balusters over open parts or voids, but kept solid over solid parts, such as pilasters, for a continued range of balusters cannot be proposed to stand alone against high winds; they would be liable to be lopped down in a row if there were not solid parts at due distances intermixed, which solid parts are in the form of pedestals, and may be in length as long as the frieze below where pilasters are double, as in our case, for double pilasters may have one united pedestal, as they have one entablature and one frieze extended over both. But now, in the inward angles, where the pilasters cannot be doubled as before they were, the two voids or more open parts would be in the angle, with one small pilaster between them, and create a very disagreeable mixture. I am further to observe that there is already over the entablature a proper plinth, which regularly terminates the building; and as no provision was originally made in my plan for a balustrade, the setting up one in such a confused manner over the plinth must apparently break into the harmony of the whole machine, and, in this particular case, be contrary to the principles of architecture. The like objections as to some other ornaments, suppose of vases, for they will be double upon the solids; but in the inward angles there will be scarce room for one, though each of them be about 2 feet 9 inches at bottom and 9 feet high. Yet these will appear contemptible below, and bigger we cannot make them unless we fall into the crime of false bearing, which artisans of the lowest rank will have sense enough to condemn. My opinion, therefore, is to have statues erected on the four pediments only, which will be a most proper, noble and sufficient ornament to the whole fabric, and was never omitted in the best ancient Greek and Roman architecture; the principles of which, throughout all my schemes of this colossal structure, I have religiously endeavoured to follow; and if I glory it is in the singular mercy of God, who has enabled me to begin and finish my great work so conformable to the ancient model. The pedestals for the statues I have already laid in the building, which now stand naked for want of their acroteria."

The Elevation in Architecture.

The elevation is to a building what the countenance is to the mind, and either prepossesses in its favour or prejudices with dislike. There are two principles of composition for elevations, the horizontal and the vertical. One of these must predominate. In the Classic buildings of antiquity the former prevailed. The latter arose in the decline of Roman architecture, is triumphant in the edifices of Mediæval art, and reigns throughout with the upshooting tendency in the buildings of the Eastern world, as in the minarets of the Mohammedan and the pagodas of the Chinese.

Microscopic Criticism.

If a difference of size in parts or details exist in a building and be not discoverable unless one takes a compass, a rule, a square, or a level, they are no longer defects. Buildings are not made for measurement but delight. When these discrepancies escape the eye and minute examination can alone detect the irregularity, the beauty of the whole does not cease to affect us. In the Pantheon the angular columns are anti-Vitruvian, being smaller, instead of larger, than the others. At the top of the pediment there is a double modillion; and on one side of the sloping cornice twenty-four modillions, on the other twenty-two. "Bravo," says Milizia, "to him who has counted them, but pitiful-bravo to him who turns up his nose at such microscopic criticism."

NOTES AND COMMENTS.

LOVERS of antiquity are compelled for the sake of consistency to advocate the preservation of trees that are dead. If, as SHAKESPEARE says, ruin can teach us to ruminate, they will ask what more fitting place for the exercise than a forest, "where wasteful time debateth with decay"? But respect should also be given to the infinitely more important principles of life and growth, unless we wish to convert the world into a huge mortuary. The Corporation of London have had to think of present and future needs in the City, and the same duty was imposed on them when they took charge of Epping Forest. But that end cannot be attained in streets or groves without the removal of things that can no longer be of use. There are people who would have Epping Forest neglected like a prehistoric forest, and they have raised an outcry because it was proposed to plant in order to provide greenwoods for a future time. The Corporation, who, of course, are not indifferent to sylvan beauty, have called in five experts, viz. Messrs. A. B. FREEMAN-MITFORD, W. SEHLICH, A. W. WEBSTER, W. ROBINSON, and J. ANDERSON to report on the operations which have been carried out. Their report, which has appeared, states that the beauty of the landscape in and around the forest might be enhanced by making judicious clearings, while the glades already in existence should be increased in number. It is also suggested that bold clearances should be made in the pollard hornbeams, and that the fine pollard oaks should be carefully preserved. In Hawk Wood the trees are not such as would be improved by wholesale thinning, and it would be wise to take out no trees except those which are dying or those stunted specimens which are injuring others. Monk Wood will need no further thinning for many years to come, and the same applies to High Beech. In Theydon High Wood moderate and periodic thinning is desirable. In conclusion they state that they are not prepared to endorse the strictures which have been passed upon the work carried out in the forest, being of opinion that much has been done judiciously and well. In some instances they do not approve of the whole of the action of the authorities, while in others they consider more might have been done. They are certain, however, that the authorities have been actuated by a desire to preserve the finest features of the forest. The report may be said to endorse the views of the Corporation. In criticising an undertaking which depends upon the principles of the picturesque there must be differences of opinion, but it is evident the forest may be safely left to the care of the Corporation.

THE old civil law allowed a finder to retain any treasure he might discover on his own land; but when obtained on another man's land the finder was allowed a half, and the owner of the ground another half. The rule applied in cases where an emperor or a prince was in the latter position. Subsequently all treasure trove was accepted as belonging to the ruler of the state. In England a sort of compromise was arranged. The treasure became royal property only in cases where there was no possibility of discovering the depositors. In modern times, if the objects found have archaeological or artistic interest, they are sent to a museum, and the finders are rewarded if they desire. Little sympathy should therefore be shown to those who have made away with some of the Saxon coins and the gold and silver ornaments which were lately unearthed in Douglas, Isle of Man. The police have succeeded in obtaining some of the treasure, but probably the most valuable part is still missing. Sir JAMES GELL, the Manx Attorney-General, has had to order a jury to be empanelled, in the hope that by an investigation of the circumstances some clue might be afforded to the treasure. It appears the coins and jewellery were turned up with the pick during the excavations for the foundation of a house. At first they were supposed to have little value; some were cast out among rubbish. The labourer had to admit there were two or three dozen bracelets and rings besides numerous coins, and he produced before the jury several samples. A doctor and a clergyman obtained a part of the treasure, but they surrendered it to the police without delay. All that was gained by the inquiry was the announcement that there was risk in keeping any of the objects, and it remains to be seen whether further meetings of the jury will be more suc-

cessful. The lady who owns the ground also claims the treasure against the Crown, and the finder also professes to have a right to it. As Manx law and custom do not always correspond with those of England, there may be a long legal contest before the ownership is settled.

LECTURERS on geology have always a fertile subject in descanting on the waste of money which follows attempts to execute works below the earth's surface without consulting geologists. It is always easy to be wise after the event, and strata are often so irregular that they cannot be diagnosed until large sums are expended on experiments. In Worthing a failure has just occurred which neither geologists, engineers nor contractors could have foreseen. On account of the illness which made the town a desert last year, efforts are being made to improve its sanitary condition. A new water-supply is to be provided. It was decided to sink the well near a spot where the chalk is so close to the surface as to be revealed by every cart-track. But by one of those freaks which are too well known in works, the chalk was not tapped at the site of the well until about 70 feet had been reached. It was also assumed that the ground in which the mains were to be laid would be chalk, but it was found to be full of flints, which were not easily removed, and the excavation is therefore costly. As the whole of the surprises have occurred within a very limited area, amateurs may say there was not sufficient foresight exercised; but geology as a science is always weak unless when it has to deal with formations on a grand scale.

It is satisfactory to find the Lord Chief Justice of Ireland proposing that a contractor's case should be referred to arbitration. In Ireland and Scotland the spirit to which DANDIE DINMONT confessed is very potent, and men find quarrel in a straw for the sake of the prestige which comes from a long course of litigation. In the case before the Chief Justice the plaintiff sought to recover £1,774*l.* 12*s.* 9*d.* for work and labour done, materials supplied, and money expended in the construction and maintenance of water-works for the Corporation of the city of Limerick and for pumping. The defendants stated that the work was done under a special contract, and except as to £184*l.*, which was lodged in court, they did not owe the plaintiff anything. They counter-claim for £3,210*l.* in respect of an alleged breach of contract on the part of the plaintiff in carrying out the works. The Chief Justice considered that if all the legal points involved were pursued, the costs would be enormous. The case, too, said his lordship, might eventually be taken to the House of Lords, and by the time it came on for determination, that tribunal might not exist. The parties prudently agreed to refer the case to two arbitrators, viz. Mr. W. SPENCE and Mr. J. TURNBULL, jun., with power to call in an umpire in case they should be unable to agree as to the amount to be paid to the plaintiff in respect of extra work. The umpire is to be selected by the President of the Institution of Mechanical Engineers, and the inquiry is to be held in Limerick. Arbitration is costly; but in this case it will probably be economical if compared with the expense of trials in the Courts. The words of the Irish Chief Justice might well be taken to heart in other cases, especially as the luxury of a contest in the House of Lords may shortly be not within the reach of those who are willing to pay heavily for the enjoyment.

THERE is so strong a desire for reconstruction in general amongst Frenchmen that nobody will be surprised at the project of M. QUENTIN-BOUCHART, which is to take down the Palais de l'Industrie in the Champs Elysées, where the Salon Exhibitions are held, and to rebuild it in the same proportions but in a better style. The new building could then become one of the attractions of the International Exhibition of 1900. The Palais de l'Industrie was erected for the International Exhibition of 1855, from designs by M. CENDRIER. The great hall, or enclosed garden, which is now used for exhibiting the sculpture, suggests the influence of PAXTON's building in Hyde Park. It was not intended for the display of works of art—in 1855 the Palais des Beaux-Arts was placed elsewhere—and this fact becomes occasionally too apparent during the Salon Exhibitions.

ILLUSTRATIONS.

TUDOR CHAMBERS, 54 AND 55 CORNHILL.

THE illustration we publish of this building is taken from a water-colour drawing by the architect, Mr. ERNEST RUNTZ, of 22 Moorgate Street. The site, which is prominently situated in Cornhill, adjoining the main entrance to St. Peter's Church and the London and Midland Bank, although not having a large area, has an extensive frontage, the ground-floor portion and basement being appropriated entirely for shop purposes, and the entrance for the office portion, with lift to the upper floors, being in St. Peter's Alley. The building is to be faced with the so-called pink terra-cotta, but in this case no effort will be made at uniformity, but rather variety in the shades of the finished material. By adopting this course it is anticipated that the general harmony of the building will be greatly improved. Certainly it will be a useful experiment, and will be watched with interest by architects who favour the material in question. From an artistic point of view, we are of opinion that it is likely to prove very satisfactory. The style adopted by the architect is a somewhat free treatment of Tudor work, refining much of the ornament in the direction of Italian Renaissance. The building, although designed for letting as shops and offices, could be easily adapted for the occupation, as a branch, of some large insurance or other company, for which purpose it will probably be used, as its position is unique. The terra-cotta work is being carried out by Messrs. DOULTONS, and the modelling has been under the supervision of Mr. NEATBY, who has caught the spirit of the detail in a masterly manner. The general contract is in the hands of Messrs. COLLS & SONS, of 5 Coleman Street, and the works are to be commenced forthwith.

SELECTED DESIGN FOR NEW MEAT MARKET AND SLAUGHTER-HOUSES FOR THE CITY OF BIRMINGHAM.

WE publish this week reproductions of the elevations and plans by Messrs. ESSEX, NICOL & GOODMAN, which have been adopted by the Birmingham Corporation for the new markets. It is not often architects are allowed an opportunity in this country to prepare similar plans, and therefore most of the works on the subject are by foreigners. As Messrs. ESSEX, NICOL & GOODMAN have taken great pains to study those works as well as the foreign examples they describe, our readers will be glad to have the elaborate description which accompanied the plans, and which explains the principles on which they were based:—

1. Realising the importance of placing all the slaughtering departments on one level, those selected to be placed on the meat market level are the three retail slaughter-houses, wholesale slaughter-houses, pig lairs, triperies or offal houses, cattle and sheep yards and gangways, leaving ample open space between same.

2. The cattle and sheep lairs are placed over the slaughter-houses, the entrances, one on each side from the streets adjoining, communicate direct by inclined ways from the entrance yards, and from the lairs to the pens in rear of the slaughter-houses by separate inclines; the animals are thus entirely isolated from the working parts until wanted, and are always moved in one direction.

3. The working spaces are in single rows, and as on the retail side there is insufficient length for all in one line, the slaughter-house for calves and sheep is placed in rear of that for beasts; this arrangement has the advantage of each allotment having a standing space for butcher's cart in the roadway and ample room for others to pass.

4. As the land falls towards the river Rea, advantage of this is taken by raising the sheep slaughter-house floor and lowering the roadway between the sheep and beast retail slaughter-house, thus obtaining a lower ground floor, the greater part being above the street levels.

5. The yard on the retail side is thus upon the present solid surface, and the subway under meat market only a few feet under that.

6. An examination of the plans will show how capable this plan is of extension on the retail side, as by repeating the alternate blocks of sheep and beast slaughter-houses, with yards and roadways between, and continuing the carcase roadways to the meat market, any future extension will be part of the same design.

7. As a general model for a good working abattoir the

establishments built during the period of Napoleon I. in Paris have been used by Architects who have been entrusted with the erection of abattoirs, and may with advantage be followed in this case. For our information we have obtained these plans, and others that closely follow the same arrangement. At Buda Pesth there is a central cold-room which takes the place of the meat market in your scheme. Hamburg we consider to be the most perfect modern example visited by us; the working details of every department have been studied by us, and the width of the spaces allotted to the working departments have been adopted in this design.

From the above remarks it may be concluded that we have not attempted to produce a novel design, but rather to find out established and fixed principles and apply them to the given circumstances.

A. THE MEAT MARKET.—The position of the meat market is that suggested by the committee, with roadways on either side. Additional doorways are introduced for the overhead travelling tracks and jennies. The windows throughout this are arranged vertically in the walls and roof, glazed in iron frames, with two parts to open as hoppers for inlet of fresh air. The outlets are the louvres in roof. The eaves project 5 feet over the line of the wall, to keep out the direct rays of the sun; the roof lights are continuous, having the eaves projected 4 feet. The roof trusses are framed up with steel lattice girders and joists. The flat will be laid with a granolithic flooring, spanning from girder to girder, and on the top of this will be spread gas-breeze concrete with falls to the eaves, covered with impervious asphalt. The sloping part of the roof will be laid with red pantiles similar to those in the Birmingham Council-house. At the end of the market adjoining Bradford Street a small portion of the ground-floor area is occupied by the inspectors' and collectors' offices and staircases to the superintendent's office and official rooms over same. Outside the market adjoining these offices is placed the caretaker's residence, which is also in close proximity to the official block and the Corporation stable and van yard.

FITTINGS AND GEARING.—The fittings and gearing shown and which we would propose using are on the most modern and approved system, and by referring to the detailed drawings it will be understood how simple they are in working. The system of overhead travellers can be taken wherever required, and as the turning points require no handles they may be placed anywhere, and they may be fitted so as to suit any class of trade. Over the market spaces or slaughter-houses two angle iron travelling tracks are suspended at a few inches apart, forming right-angle junctions; between these angle irons are suspended the travelling jennies, which are carried by a pair of small wheels on the top of same; these are placed at the most convenient height for conveying beast carcases, and may be slightly inclined to suit the working; sheep and pigs and smaller animals would be hung by lengthening hooks for three, four or six at a time from the same jennies. At each right-angled junction the jenny hook is slightly checked by dropping into the space between the two tracks, and if it is required to proceed in either of the four directions from any particular point it is only necessary to twist the jenny round and the wheels will adjust themselves. The rails can be used partly for fixed hooks and partly for travelling hooks, so that carcases may be run straight into the various market spaces and remain there, or be taken off and put upon the fixed hooks, and the jennies returned to the slaughter-house.

It will be observed from the plans that the various avenues and blocks of spaces allotted to the butchers have in every case two sides exposed to the roadway; this is to give as much outward hanging space as possible. The whole system is suspended from lattice steel girders, forming a gridiron for hanging rods at about 12 feet apart in every direction. The carcases for the cold stores would be run on the same hooks, and having been conveyed to the lifts would descend and be taken inside each chill-room, where the carcases can remain on the jennies until required, or be removed to the fixed hooks. The point kept in view in arranging these fittings is to have every traveller of the same pattern, so that the whole may be interchangeable.

1. INSTALLATION FOR CATTLE.—*Wholesale Slaughtering Stalls.*—Twenty stalls, each consisting of two patent self-lowering self-sustaining rope hoists for fixing into wall, with requisite guide sheaves, wire rope, rings, iron beams with hooks, brackets, columns, trellis partitions. *Retail Slaughtering Stalls.*—Twenty patent self-lowering, self-sustaining rope hoists for fixing against the wall, with the requisite guide sheaves, wire rope and rings.

2. COMPLETE OVERHEAD TRACK FROM THE SLAUGHTERING STALLS TO THE MARKET.—About 2,000 yards of track, with necessary girders, brackets and hangers, fifty travelling jennies and hanging-bars.

3. FOR SHEEP AND CALVES.—Two hundred yards of flat bar with 500 steel hooks and two brackets.

4. FOR PIGS.—Five independent revolving cranes, or travelling crabs, if preferred; five scalding tubs, with fittings

complete; ten iron shaving tables; iron beams, with 396 fast and 180 loose steel hooks, travelling track; ten travelling crabs; nineteen columns, cross girders, &c.

5. WASHING ENTRAILS.—Thirty-two cells, each consisting of two tubs, with fittings complete, iron beams with 350 movable steel hooks and brackets.

6. PIG PENS.—Ten patent doors opening at either end; sixteen doors opening at one end; fifty-eight cast-iron columns and the necessary trellis partitions.

7. MEAT CELLS.—Eighty-four complete meat cells, consisting of iron beams with fast and loose galvanised steel hooks, wrought-iron pillars and cross bars, trellis partitions built of angle iron and flat iron and stout galvanised wire netting, galvanised iron frame and door.

8. DISEASED CATTLE.—Three patent self-lowering self-sustaining rope hoists, with the requisite guide sheaves, wire rope, hanging bars, rings, one scalding tub, one track and travelling crab, beam with galvanised hooks and brackets.

9. SUNDRIES.—Consisting chiefly of cars, tables, stands, blood-collecting vessels, buckets, &c. The whole fittings, in weight about 170 tons, would cost about 5,000*l*. Each space allotted to a butcher can have a convenient office arrangement as shown, consisting of a lower office, with desk-room for one or more persons, and a small spiral iron staircase to a room over, which could conveniently contain three or four persons.

B. SLAUGHTER-HOUSES FOR WHOLESALE BUTCHERS.—These are placed in the position shown on your plan, and are spaced so as to give twenty separate houses, divided by iron grills, and are sufficiently wide and fitted up so as to allow two slaughter-men working in them at the same time; and also space for one killing sheep or calves. There is one doorway to each slaughter-house from the yard, with a pen at either side, so that each slaughterman can have his next animal penned on his own side; the killing points are immediately within the doorway about 2 feet 6 inches from the jamb, and we suggest that the Manchester pattern be adopted. The arrangement of the hanging fittings will give ample space for setting before the carcasses are removed into the meat market; extra rails can be introduced to suit the special trade of any butcher. On this side of the market hall the animals are brought into the slaughter-houses on the same level as that of the adjoining yard, they will be conveyed within a 6-foot wide gangway, railed off from yard with gates at convenient points.

C. LAIRAGE FOR SHEEP AND BEASTS FOR WHOLESALE BUTCHERS.—These are placed over the slaughter-houses and partly over the block of buildings adjoining Sherlock Street on the same level; we do not consider that there is sufficient area over the slaughter-houses to lair the number of beasts asked for unless the sheep are placed in a storey over the beasts, which would increase the height of the buildings and interfere with the lighting of the market hall. The approach to the lairs is from Sherlock Street into a convenient yard, where the animals can be examined; the sheep would pass along the inclines on the left to the lairs over the block of buildings next Sherlock Street; this is one long hall with a central avenue, divided up into convenient pens with racks between. The arrangement proposed is to conduct the animals through the layers one way only, so that animals entering will never have to meet those coming into the slaughter-houses; the exit from the lairs to the slaughter-houses is at the further end from the entrance, and has similar inclines communicating with the corridor above described in connection with the slaughter-houses. To each sheep is allotted a space of 6 feet superficial and 1 foot in length along the feeding rack. In connection with these lairs the fodder store is placed over the entrance yard, and is an isolated fireproof apartment with iron doors; from this store the fodder and litter will be meted out to the various butchers. The beast lairs are arranged over the slaughter-houses and projecting over the pens in the rear of the same; they are arranged in one long hall with a corridor at one side, the lairs being divided up as is usually done in byres, that is, with tying spaces right and left, giving 24 feet superficial to each animal, and a corridor between the rows of animals; these lairs would each contain ten animals, each block would be closed by a gate and may be used as loose boxes. Between each lair a feeding and watering passage is arranged. Water will be laid on at the end of each feeding corridor, and a cast-iron trough with hinged cover running towards the outside wall, with drain at the outer end passing through the wall to the court below. The manure drain from these lairs would be taken below the floor level and covered with gratings, and having catch pits at various points and drains taken down into the main open gutter in yard. The roof is open timbered upon iron trusses, giving air space and ventilation to the animals; special ventilators are placed along the roof.

D. SLAUGHTER-HALLS FOR RETAIL, &c., BUTCHERS.—These slaughter halls are arranged so as to give as much air-space and open working as possible, and in this respect they will be similar to the halls at Hamburg, and in our own country on a smaller scale at Bradford. The points we have aimed at are to give as much slaughtering accommodation as possible in

single rows; we find it impossible, without crowding, to obtain the necessary accommodation in one row, therefore we have placed the sheep in rear of the beasts as regards the market hall, but having equally convenient access by the addition to carcass roadway.

The pig slaughtering-hall is placed at the Cheapside end of the carcass roadway; it is conveniently near the pig lairs, which are on the street level.

Another point which we have kept in view is not only the convenience of passing the meat from the slaughter-houses by the overhead runners into the market hall, but that every butcher who uses the killing spaces has a frontage to a roadway and standing space for his own cart, so that there should be no jostling or inconvenience at loading-up points. The slaughter-hall for beasts has a door to each pair of slaughtermen, as on the wholesale side, each slaughterman having a pen communicating with the corridor outside, which in this case is above the level of the roadway. The corridor is formed by projecting the flooring upon girders on cantilevers. The overhead travelling jennies and gearing generally is the same as that on the wholesale side.

The sheep slaughter-hall has a single door to each allotted space, with separate pen to each entering from the corridor in the court between the sheep slaughter-hall and the beast slaughter-hall. The sheep hanging hooks are arranged on each side of each allotment, and the overhead travelling gear passes the front of each allotment with a short piece at right angles, so that a number of sheep may be arranged upon the hanging hooks ready for travelling into the market as may be required, in addition to the ordinary sheep hanging hooks at each side.

The pig slaughter-hall, which is in the same line as the beasts, is of the same widths, and is approached from a similar corridor in the rear, the pigs passing across a bridge from layers on the opposite side of the cartway. It is proposed that they be struck in the enclosed pens immediately outside the slaughter-hall, as is done at Bradford, and that they should be afterwards picked up upon the travelling-crane and placed in the scalding vat, &c., afterwards being finished off upon the dressing hook, which may be raised or lowered for convenience by a pulley block. We have provided one scalding tank to each pair of slaughtermen, but one set of overhead travelling crabs to each. This slaughter-hall is made higher than the others; on the roof are ventilators to carry away the steam arising from the scalding tanks. The sheep and beasts slaughter-halls are divided from the carcass roadway by a granolithic wall 8 feet high, having doorways to each allotment.

The lairage for the animals to be slaughtered on the retail side is placed over each slaughter-house. The pigs are laired on the same level as their slaughter-hall; on leaving the street the animals enter a yard similar to that on the wholesale side; from this yard two inclined gangways are provided to convey the animals to their respective layers; the pigs pass through on the same level. In the pig lair is provided a small meat room and feeding pen. The lairs for sheep are similar to those described on the wholesale side; the animals pass along through the lairs down the inclined gangway on the other side to the corridor behind the slaughter-halls. This also applies to the beasts. The fodder store is placed over the pig lairs and conveniently near the entrance yard for animals; it is also a fireproof building, with iron doors and windows, and being placed on the same level as the lairs it is convenient for access, and the fodder and litter would be meted out as before described.

E. DEPARTMENT FOR THE STORAGE OR COLLECTION OF ROPES, &c.—In arranging this department, we have placed the tripe-dressing and boiling and offal-houses on the same level as the slaughter-houses, and the department for the collection of ropes, feet, heads, skins, &c., can as conveniently be placed on a lower level on the retail side, or on the opposite side of the cartway in the wholesale. These triperies or offal-houses, as they have to deal with a large number of small articles, must necessarily cover considerable space, and we think it advisable that each side, viz. the wholesale and retail, should be provided with separate departments for this work; that for the retail is placed adjoining Bradford Street; the offals can be readily run in upon a small truck. That on the wholesale side is placed along Sherlock Street, and, although we consider it may be sufficiently large for present requirements, we suggest that when the lease of the part coloured blue on your plan is obtained, that another offal-house be erected so as to complete the design. Triperies are arranged so as to accommodate those who may require lock-up apartments, and also to suit those who may be satisfied to work in the open hall. The small rooms are divided off by wooden partitions 7 feet 6 inches high, with two steam jacketted boilers, gut hooks, scraping boards and sinks complete in themselves; whilst in the open hall they are arranged along the walls, scraping-boards and sinks and jacketted boiling pans divided into four, so that four persons may use the same pot. Each of these triperies are well lit, and have ample means of cross ventilation as the windows are on both sides. The storage of ropes, feet,

hides, &c., are arranged on the floor underneath the beasts' slaughter-house, and are approached from the cartway entrance from Cheapside.

We have shown what we consider at present to be a sufficient number of these stores, but there is ample room for extending this accommodation. The departments for blood separation are in duplicate, so that it is unnecessary to carry the fresh blood far; after the clot is separated it is removed to the blood manure machine from the wholesale side by the subway. The blood separating for the retail side adjoins the blood manure machine. Both these departments are cross ventilated and well lit.

F. COLD STORES.—The storage chambers are placed in a block underneath the market hall, and isolated by a corridor or air-passage from the surrounding earth. The floor between the market hall and the cold stores would be sub-ceiled or hollow, and contain cold-air passages to each cold store; underneath the cold stores and between them and the ground there is also a series of air-passages. The hollow walls surrounding the cold stores underneath and over same to be packed with silicate cotton. The approach to these cold stores is either from the subway which communicates from the wholesale and retail, or by the lifts, two on either side of the market hall, by which carcasses can be readily dropped and run along the corridors on the travelling gear to any apartment. Inclined ways are also provided to the doorways of the market hall. The passages around the cold stores are lit by area windows from the covered roadways. On the sheets of details are shown the separate compartments; the jennies would be continued into these stores.

G. ENGINE AND MACHINERY DEPARTMENT.—These are placed so as to adjoin the refrigerating plant. A steam boiler for generating low-pressure steam for boiling up water by the injection of steam is provided and pipes taken to all the slaughter-halls. The pumping department is placed immediately adjoining the boilers and the tank for the artesian well, &c. The water tower will contain the cold-water storage tanks—is also used as the chimney stack, which is in the centre of it; there will be accommodation for the storage of sufficient water to allow for an average use of forty-five gallons for each animal slaughtered—it has been computed that every animal slaughtered requires about this quantity.

H. MESS ROOMS, &c.—The mess room for the market officials adjoins the offices, and is in communication with the caretaker's house; that for slaughtermen is placed over one end of the market hall. We have selected this position as being light and airy and convenient, and no detriment to the market hall itself.

The closets and lavatories are provided for in four separate blocks—one for officials and market-keepers, two for slaughtermen and one for the general public—at each entrance to the covered carcase roadways; they are placed underneath the roadway so that there may be no objection to them, and they can there be made sufficiently large to give accommodation for lockers for the men and for wash and brush up; access is obtained by a short stair from the roadways and also from the staircase at the ends of the market hall.

I. APPARATUS FOR DESTROYING CONDEMNED MEAT.—This apparatus is placed on the retail side entering from the courtyard and underneath the sheep slaughter-house; it consists of a condemned lair, a slaughter-house with all necessary apparatus, and a room for the meat-destroyer; this room adjoins that of the blood-manure machine. Manure repositories are placed in the yards with entrances at the various floors from the galleries, lairs, slaughter-houses, &c.; they are continued upwards of an equal height and are finished with open ventilator-tops.

DRAINAGE.—The system of drainage is shown on the plans and sections, and consists of four large reservoirs or settling tanks placed in each yard, into which will be directed the open drains, with grated covers. Each slaughter-house will have an open channel for conveying water and bits outside the doors of each allotted space in the rear; it will then be taken down to the court level, where it will pass along the cast-iron channels with grated covers to the settling tanks; these tanks will have overflows with falls to the drains in Cheapside and Bradford Street. The tops of these settling tanks will be hinged, so that they may be cleaned out daily. The soil drains from lavatories will be taken by a separate system to main sewers. The rain-water system of drainage is kept entirely clear of this sewage system, and as sufficient water will have to be used daily for carrying the sewage and refuse to the settling tanks, rain-water tanks are provided, so that this water may be automatically used in flushing, &c.

ROADWAYS.—The roadways, yards and cartways are arranged so that they may not interfere with the animal traffic; the main court on the retail side is approached from Cheapside, and gives access to every department on this side, as well as to the cold stores, whereas the entrance from Sherlock Street on the wholesale side gives ample accommodation for carts independently of the carcase roadways; in fact, this scheme which

we lay before you is based upon the principle that as the site is restricted, it is necessary to economise and proportion to each department the accommodation required, and by maintaining the system we have shown on this plan we believe a good working abattoir would be the result.

VENTILATION.—Having carefully considered the question of ventilation and provided for thorough and cross ventilation throughout the slaughtering halls and lairs by means of louvred windows and roof outlets, yet we consider that a system of ventilation by propulsion would be advisable in the basements and in the meat market, and we would suggest that the chilled air be blown through shafts to outlets by the fans at work in connection with the refrigerating plant.

METHOD OF CONSTRUCTION.

Walls.—The construction generally to be fire-resisting, woodwork only being used where necessary. The walls to be of good sound brickwork, with picked red facing to those elevations exposed to streets, and buff terra-cotta dressings, sills, lintels, &c. So as not to obstruct the space in market, &c., with buttresses, open light and deep lattice-girders are introduced to stay the building over the travelling jenny level; the offices will be supported from these.

Floors.—The floors throughout to be of breeze concrete, arched on soffit and finished with granolithic paving, and skirting of same carried 12 inches up the walls.

Glazed Bricks.—The inside walls of the meat market and slaughter-houses to be lined with white glazed bricks, as suggested, and the carcase roadways on ground floor, and engine-room and corridor round cold stores and the cold stores with brown salt glazed bricks.

Steelwork.—The floors and roofs to be carried by steel girders, lattice-girders and trusses; the roofs with pitch-pine rafters and close boarding; the whole of roofs to be covered with red pantiles with overlapping joints. The roof plumber-work and down-spouts for rain-water to be of fine cast-iron with flashings of 5-lb. lead.

Doors.—The doors throughout the slaughter-houses, including the screen doors between carcase roadways and slaughter-houses, to be 2½ inches thick, framed and braced with 1½-inch V-jointed panelling (all internal doors having the upper panels filled with open grills), hung either with rollers overhead or hooks and long bands. The doors to fodder stores to be of sheet iron.

Roadways.—The roadways for carts to be laid with wood-block paving laid in pitch upon concrete beds. The other roadways and footpaths to be brought up to levels with solid excavation and concrete bottoming, and finished with granolithic paving with falls to gullies.

Offices and Caretaker's Residence, &c.—These to be finished in adamant plaster, with doors, architraves and usual house finishings.

Lavatories.—To be lined throughout with brown salt glazed bricks, and pitch-pine divisions to closets, those for workmen with lock-up cupboard, &c. The sanitary fittings to be of glazed earthenware.

Separate Drains for Rain-water, Slaughter-houses and Sewage.—The rain-water drains to tanks to be of glazed earthenware, with all necessary junctions, &c. The drains in slaughter-houses to be open channels in the flooring, and when continued outside to be of cast-iron troughs, covered with iron hinged gratings to catch-pits. The sewer drains to be of glazed earthenware.

Cattle and Sheep Gangways and Gates.—These to be supported upon and cantilevered out with steel joists, and to have granolithic flooring, with wood bar steps for foothold, and to have framed steel railings and gates, with drawn tube bars and hooks and fixing blocks of granolithic stone.

Lairs and Pens.—The fittings to lairs and pens to be of drawn tube screwed into cast-iron newel posts, and gates to pens secured to granolithic blocks. The cattle lairs to have drinking-troughs and hay-racks, the sheep to have feeding-racks, and the pigs a feeding-pen with boozing-trough, &c.

Cold Water Supply.—The cisterns in water tower to be connected throughout the buildings, with iron pipes to the various smaller cisterns and stand-pipes in yards.

Hot Supplies.—Each slaughter-house, hall and tripery to have hot water laid on from cisterns placed at convenient points; these cisterns to be heated by steam coils.

The buildings will take over two years to construct, and it is intended that they be opened before the end of 1896. The total cost will be 50,000*l*.

An Exhibition of pictures, drawings in black and white, wood engraving, printing, bookbinding, leather work, wood-carving, furniture, and metalwork, designed and executed by members and associates of the Society of the Quest and Guild of Handicraft, has been held in Birmingham this week.

A VISIT TO CLUNY.—II.
